Strategies of cooperation and punishment among students and clerical workers

Maria Bigoni, Gabriele Camera, and Marco Casari*

Abstract

We study individual behavior of students and workers in an experiment where they repeatedly faced with the same cooperative task. The data show that clerical workers differ from college students in overall cooperation rates, strategies adopted, and use of punishment opportunities. Students cooperate more than workers, and cooperation increases in both subject pools when a personal punishment option is available. Students are less likely than workers to adopt strategies of unconditional defection and more likely to select strategies of conditional cooperation. Finally, students are more likely than workers to sanction uncooperative behavior with decentralized punishment and also personal punishment when available.

Keywords: Non-standard subject pools, prisoner's dilemma, personal punishment, artefactual field experiment, stranger matching.

JEL codes: C90, C70, D80

1 Introduction

Cooperation—acting for the joint benefit of a group—is a key issue in the social and behavioral sciences and has been extensively studied by experimental economists. Achieving cooperation is especially challenging when individuals cannot develop personal ties and interact as “strangers.” Two aspects of cooperation in groups of strangers are still relatively unexplored in experiments. First, whether results that emerge from studies based on a typical population of undergraduate students can be generalized to *non-standard* subject pools characterized by a wider array of life and work experiences. Second, if and how adding a personal punishment opportunity to a standard social dilemma affects the strategies adopted at the *individual* level.

We address these aspects related to methodological issues and to substantive issues by carrying out a study of cooperation when the task is repeated indefinitely and subjects could not rely on reputation. The patterns of behavior of college students are compared to those of white-collar workers in treatments with and without a personal punishment opportunity. The benchmark subject pool in the experiment consisted of undergraduate students from various disciplines at Purdue University, a large U.S. university. The non-standard subject pool comprised clerical workers employed as staff throughout Purdue University. These workers were mostly long-time local residents, and exhibited a wide variation in age and educational backgrounds.

In the experiment pairs of subjects played a prisoner’s dilemma either with or without the opportunity to engage in personal punishment. They interacted for an indefinite number of periods as strangers: subjects neither could identify the person they were matched with nor see their history of play. According to folk theorem-type results, this setting admits multiple equilibria including one with 100% cooperation (Kandori, 1992, Ellison, 1994). Indefinite

repetition helps to overcome the short-run temptation to cheat others if players adopt a norm of behavior based on the threat of relentless decentralized punishment, i.e., if they *permanently* cease to cooperate after seeing just one defection, i.e., grim trigger strategy. Here, personal punishment is theoretically neither necessary nor sufficient to sustain cooperation. Evidence from previous studies indicates that cooperation levels are low when subjects do not know each other and cannot build reputations (e.g., Ostrom, 2010) and increase substantially when there are personal punishment opportunities (e.g., Ostrom, et al. 1992, Fehr and Gaechter, 2000).

Our design closely reflects the decentralized trading environment in Kandori (1992) and Ellison (1994). This generates theoretical predictions that serve as a reference in the interpretation of the empirical findings. In the paper, we assess (i) the strategies adopted by individuals in each subject pool, (ii) how students and workers differ in their ability to achieve cooperation, given that many cooperation rates are supported in equilibrium, and (iii) how the opportunity to *also* inflict a personal punishment affects individual strategies.

The design is as follows. Each participant played a supergame of indefinite duration within a group of four subjects. In every period, the group was randomly partitioned into two pairs of subjects and every pair played a prisoner's dilemma (PD). The PD is the standard platform in the literature for studies about cooperation. The interaction was anonymous and subjects could only observe actions and outcomes in their own pair. Hence, though each group interacted repeatedly, this design made it impossible for a single participant to build a reputation. This excludes reputation-based strategies as an explanation for cooperation, and brings to the forefront strategies that do not discriminate individuals based on their identity. As an additional advantage, this stranger design facilitates the identification of strategies because it exposes participants to a variety of counterparts.

In the experiment we also introduce the possibility to adopt personal punishment. This amounts to add a costly opportunity to immediately respond to a counterpart's action by lowering her payoff. Cooperators and defectors alike could be punished. We are especially interested in studying if and how subjects use personal punishment to complement or to substitute for informal sanctioning schemes that rely on future defections.

In previous work (Camera, Casari, and Bigoni, 2011) we questioned the empirical validity of the theoretical notion that play is homogeneous and that subjects implicitly coordinate on full cooperation when such equilibrium is available. That study revealed that only the behavior of one out of four subjects is consistent with the use of the grim trigger strategy. It also revealed that as subjects gained experience with the game, they kept experimenting with different strategies, and managed neither to achieve full cooperation nor to coordinate on cooperative strategies.

This paper moves forward the study of equilibrium selection and individual strategy adoption in two directions. First, it explicitly compares aggregate and individual behavior of two diverse subject-pools. Second, it extends the analysis of strategies from the case where subjects can only resort to decentralized punishment, to a design in which they *also* have the opportunity to engage in personal punishment. We report substantial differences between subject pools both in aggregate and individual behavior and both in the design with and without the personal punishment opportunity. Students exhibit higher levels of aggregate cooperation than workers. Students are also less likely than workers to adopt unconditional strategies and more likely to select strategies of conditional cooperation. Finally, students are more inclined than workers to sanction defections through decentralized punishment and personal punishment, when available.

2 Related experimental literature

Our study is related to the experimental literature about differences in behavior and in strategies of subjects with different socio-demographic characteristics. One methodological question that is still open in this literature is whether results from a standard undergraduate population generalize to other populations, which is related to the external validity of experimental results (Harrison and List, 2004). There are only a few published studies on games of trust and cooperation, which compare students to non-student samples; the main message is that students are less cooperative and that age tends to be negatively correlated with cooperation.

The literature on public good games indicates that students contribute on average less than non-students. Support for this result comes from several studies involving non-student subject (e.g., Carpenter and Seki, 2006, Egas and Riedl, 2008). See also Burks et al. (2009), for a one shot prisoners' dilemma game with student and non-student population, Students tend to cooperate less than non-students also in trust and investment games; they exhibit a less trusting and trustworthy behavior (e.g., Fehr and List 2004, Bellemare and Kroeger, 2007). More in general, there is evidence that age is positively related to trust and trustworthiness (e.g., Gaechter et al., 2004, Sutter and Kocher, 2007, Hannan et al., 2002).

A growing number of experimental studies collect empirical evidence about strategies adoption in indefinitely repeated social dilemmas. Most of these studies involve a short time horizon and a subject pool of only undergraduate students (e.g., Kurzban and Houser, 2005, Engle-Warnick and Slonim, 2006, Dal Bó and Fréchette, 2009, Fudenberg et al., 2010, Davis et al., 2011). In contrast, our design is based on a game with a longer horizon with also workers' participants. It complements and extends the works in Camera and Casari (2009), on the impact of information on cooperation, and in Camera, Casari, and Bigoni (2011), on individual strategy

adoption in a standard subject pool. The main elements of novelty relative to the above two studies are as follows. First, here we study how the availability of peer punishment affects strategy adoption; peer punishment is known to strongly affect aggregate behavior, although not much is known about how it affects individual strategies. Second, we investigate whether there are any subject-pool specificities in strategy adoption and realized cooperation levels.

The experimental literature on the effects of costly personal punishment on cooperation has mostly focused on one-shot and finitely repeated social dilemmas. Subjects display a tendency to engage in costly personal punishment of others, especially defectors. Though this behavior is inconsistent with personal income maximization, it has been shown to be remarkably robust (e.g., Ostrom et al, 1992, Casari and Luini, 2009). We examine whether and how this behavioral trait impacts the strategies adopted to sustain cooperation in an indefinitely repeated game, where subjects can also use a decentralized punishment scheme to police defections.

3 Experimental design

The experiment consists of four treatments, characterized by a different combination of two treatment variables: the availability of a personal punishment option (no punishment, NP, or personal punishment, PP) and the nature of the subject pool (students or workers). Continuation probability, stage game parameters, matching protocols, and private monitoring were kept constant. The NP treatment is a baseline environment designed to study strategy selection in an indefinitely repeated prisoner dilemma among strangers, where individual reputation formation is impossible. In an additional treatment (PP treatment), we also study how behavior is influenced by the availability of punishment institutions, i.e., when subjects have the option to

use personal punishment.¹ To investigate whether realized outcomes and individual strategies adopted vary across different subject pools, we ran experiments with undergraduates and white collar workers. Below we describe stage game, continuation probability and matching protocols, which were identical across treatments.

Each participant played a supergame within a group of four persons who interacted *privately* and *anonymously*. Subjects were randomly matched in pairs in each period. Because we will employ non-cooperative equilibrium theory to develop theoretical predictions, we refer to a subject's counterpart in a pair as the "opponent." The interaction was private because subjects observed only outcomes in their pair. The interaction was anonymous because subjects could not observe identities, thus reputation building was impossible.

The stage game was the prisoners' dilemma described in Table 1. In the experiment, subjects could choose between C (=Cooperate) and D (=Defect). The parameters of the experiment were calibrated to promote some cooperative choices, which is necessary to uncover the strategies that participants adopt to support cooperative outcomes.²

	Player 1	<i>Cooperate</i>	<i>Defect</i>
Player 2			
<i>Cooperate</i>		25, 25	5, 30
<i>Defect</i>		30, 5	10, 10

Table 1: The stage game

Notes to Table 1: the labels in the instructions were Y for Cooperate and Z for Defect

A supergame (or *cycle* as in the instructions) consisted of an indefinite interaction among subjects achieved by a random continuation rule; see Roth and Murnighan (1978) or Palfrey and Rosenthal (1994). To implement this rule, at the end of each period the program drew a

¹ These two treatments respectively correspond to the *Private Monitoring* and *Private Monitoring with Personal Punishment* treatments in Camera and Casari (2009).

² The parameterization in Table 1 was selected as it scores high on the indexes proposed by Rapoport and Chammah (1965) and Roth and Murnighan (1978) that correlate with the level of cooperation in the indefinitely repeated prisoners' dilemma in a partner protocol.

random integer between 1 and 100, using a uniform distribution. The cycle continued with a draw of 95 or below. Hence, in each period a cycle continues with a constant probability $\delta=0.95$. For a risk-neutral subject δ represents the discount factor. In each period, the cycle was expected to continue for 19 additional periods. All session participants observed the same random draw, which means that cycles terminated simultaneously for all economies.

Each experimental session comprised twenty subjects and five cycles. We built twenty-five economies in each session by creating five groups of four subjects in each of the five cycles. Matching across cycles followed a perfect stranger protocol: in each cycle each group included only subjects who had neither been part of the same group in previous cycles nor were part of the same group in future cycles. Subjects were informed that no two participants would ever interact together for more than one cycle. With this matching protocol across cycles, we can consider each subject as having five distinct “lives” in a session.

In each cycle, participants in every four-subject group interacted in pairs as follows. At the beginning of each period of the cycle, the group was randomly divided into two pairs. Each subject had one third probability of meeting any other participant in each period. For the entire cycle a subject interacted exclusively with the members of her group. In each group, subjects could neither observe identities of their opponents, nor communicate with each other, nor observe histories of others. As a consequence, subjects did not share a common history.³

The PP treatment introduced the possibility of personal punishment in the baseline design. Subjects could lower the opponent’s earnings at a cost. This was done by adding a second stage to the game played in each round. The first stage was the prisoners’ dilemma in Table 1. After

³ This experimental design expands the scope of the analysis relative to designs based on two-person groups. First, subjects face a wider variety of behavior, which facilitates the empirical identification of strategies. Second, we can investigate strategies that are not based on reputation, since we can control anonymity. Third, it allows investigation of how subjects coordinate on outcomes and strategies, which is more challenging than in two-member groups.

the outcome in the prisoner's dilemma was observed, both subjects in the pair had the opportunity to pay 5 points to reduce the opponent's earnings by 10 points. These decisions were simultaneous. No one could observe outcomes or actions outside a pair, including personal punishment.

The second treatment variable is the subject pool. The experiment involved two distinct groups of subjects: 80 undergraduate students from various disciplines at Purdue University and 80 clerical workers employed as staff throughout Purdue University. Undergraduates have a strong international component, while clerical workers are mostly long-time state residents, who exhibit a wide variation in age and educational background. Table 2 reports a summary of the main demographic characteristics of the two subject pools.

We ran two sessions per treatment. Each session had 20 participants and 5 cycles. The 80 student subjects were recruited through e-mail and in-class-announcements. The 80 worker subjects were recruited through e-mails targeted to administrative and technical staff across the West Lafayette campus. Each subject participated in only one session. Some students had previously participated in other types of economics experiments, while none of the workers had. Sessions were run in the Vernon Smith Experimental Economics Lab at Purdue University. No eye contact was possible among subjects. Instructions were read aloud with copies on all desks. A copy of the instructions is in Appendix B. The experiment was programmed using z-Tree (Fischbacher, 2007). Average earnings were \$18 excluding show-up fees. A session lasted on average 84 periods for a running time of about 2 hours, including instruction reading and a quiz.⁴

⁴ Sessions took place on the following dates for NP: 21.4.05 (71) and 7.9.05 (104) with undergraduates, 29.11.05 (80) and 06.12.05 (50) with clerical workers; for PP: 28.04.05 (139) and 06.09.05 (99) with undergraduates, 8.12.05 (56) and 13.07.06 (77) with clerical workers. In parenthesis we report the total number of periods for the session. Show-up fees are as follows: students received \$5 (\$0 on 06.09.05); clerical workers received \$5 in the PP and \$10 in the NP treatments. Data of the first two sessions in treatments NP and PP are also analyzed in Camera and Casari

	Students (N=80)		Workers (N=80)	
	Average	Missing	Average	Missing
Male	53.8%	0	63.6%	3
Age	21.2	10	37.4	14
Married	5.0%	40	50.6%	3
With children	2.5%	40	53.3%	5
Gross family income > \$50,000	65.2%	57	43.5%	18
Home owner	5.0%	40	64.0%	5
Education: college or higher	10.0%	40	57.1%	3
Work experience (years)	2	0	13.5	0
Foreign born	18.9%	43	7.7%	2

Table 2. Demographic characteristics

Notes to Table 2: Data are self reported by subject in the questionnaire. Some observations are missing because subjects either did not respond, or had a different version of the questionnaire.

4 Theoretical considerations

Here we offer theoretical equilibrium considerations, based on the Folk theorem-type results proved in Kandori (1992) and Ellison (1994) for random matching economies.⁵

Consider identical players, self-regarding and risk-neutral. The stage game is a prisoner's dilemma where total surplus in the group is maximized when everyone chooses C (=efficient outcome) and hence earns $c=25$ and minimized when everyone selects D (=inefficient outcome) and earns $d=10$. The Nash equilibrium is unique and corresponds to the inefficient outcome.

Indefinite repetition of the stage game with random participants supports a large set of sequential equilibrium outcomes. We discuss two equilibria. First, the strategy “always defect” is always a sequential equilibrium because D is a best response to play of D by any randomly

(2009), which however does not analyze individual strategies. Data of all sessions of the NP treatment are also analyzed in Camera, Casari and Bigoni (2011).

⁵ Details on derivations are in the Appendix to Camera and Casari (2009).

chosen opponent. In this *inefficient* outcome everyone earns d in each period, hence earns payoff $d/(1-\delta)$. Second, if δ is sufficiently high, then 100% cooperation can be sustained in each period as a sequential equilibrium (Kandori 1992, Ellison 1994). In this *efficient* outcome every player earns payoff $c/(1-\delta)$. More precisely, let $\delta^* \in (0,1)$ be the unique value of δ that satisfies

$$\delta^2(-hd + \delta(2h - c - d - 3) - h = 0).$$

Here $h=30$ is the payoff when the player defects while the opponent cooperates. If $\delta \geq \delta^*$, then the efficient outcome is a sequential equilibrium; this sufficient condition is satisfied in all experimental treatments because $\delta=0.95 > \delta^*=0.443$.

To see how players can support the efficient outcome, consider a situation in which all players adopt the *grim trigger* strategy. This social norm is a rule of behavior that identifies desirable play and a *decentralized* punishment scheme to be implemented if a departure from desirable play is ever observed. Put simply, each player starts cooperating and keeps cooperating, unless someone defects; in that case the player switches to a punishment phase consisting of “always defect.” This triggers a contagious, indiscriminate and relentless punishment process. Although people may not ordinarily follow a grim trigger strategy in practice, theorists employ it widely when tracing the cooperation frontier in repeated games. Because defection is an absorbing state, such decentralized punishment threat ensures that no-one deviates in equilibrium as long as players sufficiently value future payoffs. This requires a sufficiently large discount factor δ . In economies of four players, the absorbing state can be reached very quickly, hence δ^* is low.

Several remarks are in order. First, due to private monitoring, T-periods punishment strategies cannot support the efficient outcome as an equilibrium; see Ellison (1994). Second,

that same paper indicates that the efficient outcome could be sustained in our experiment also by adopting contagious punishment strategies that exploit the availability of a public randomization device. This is so because in every period all session participants observed the same random integer number, which could have served as a public randomization device. Third, cooperation is risk-dominant in our design, in the following sense. Compare the strategy “always defect” to “grim trigger.” Grim trigger is risk-dominant if a player is at least indifferent to selecting it, given that everyone else is believed to select each of the two strategies with equal probability. Indifference requires $\delta = 0.763$.

Finally—and most importantly—the use of personal punishment is neither necessary nor sufficient to sustain the efficient outcome as an equilibrium in our private-monitoring economies. The personal punishment opportunity gives players the (costly) option to lower their opponents’ earnings, after observing the outcome of the prisoners’ dilemma. In one-shot interactions, using personal punishment is a dominated action because it is costly for the punisher. Given indefinite repetition, personal punishment is not theoretically necessary for two reasons. First, players can adopt the social norm based on grim trigger to sustain the efficient outcome. Second, use of personal punishment does not allow players to trigger a faster contagious process of defection, because actions cannot be observed outside a match. On the other hand, the use of personal punishment *alone* is not theoretically sufficient to sustain the efficient outcome because it is not credible, though it could be used in combination with the threat of switching to harsher punishments (e.g., a penal code-type of strategy that presumes a switch to “always defect” if a defector is not sanctioned with personal punishment). In short, standard theoretical arguments suggest that personal punishment is an irrelevant institution to sustain cooperation.

5 Estimation procedure for individual strategies

This section describes the methodology adopted for the empirical identification of the strategies employed by individuals in the experiment. The unit of observation is the sequence of all choices of a subject in a cycle (=an *individual*); we may also refer to such a sequence as one *observation*. Hence, each subject in the experiment contributed five observations to the dataset.

In this repeated game there are infinitely many strategies. The data analysis in this paper focuses on twelve strategies, some of which are consistent with equilibrium behavior while others are not (Table 3). Consider that *any* type of behavior observed in the experiment can be described by a sufficiently complex strategy. We used the following approach to select the twelve strategies. First, we have considered strategies that rely neither on personal punishment nor on personal punishment histories. As noted earlier, personal punishment is neither necessary nor sufficient to sustain the efficient outcome, hence we study the use of personal punishment separately from the behavior in the prisoner's dilemma. Second, we have included the two unconditional strategies "always defect" and "always cooperate," as well as ten conditional strategies of cooperation for which there is already some empirical support (Dal Bó and Fréchette, 2011, Fudenberg et al., 2011, Camera, Casari and Bigoni, 2011). The ten conditional strategies allow us to gauge the complexity of subjects' behavior: they include strategies that condition on short as well as on longer histories of play. We include "tit-for-tat" and "grim trigger" and eight longer-memory versions of such strategies that exhibit either a longer fuse to triggering the punishment phase, or a longer punishment phase.

Strategy	Description
<i>Unconditional</i>	
Always cooperate	Always choose C (=cooperate)
Always defect	Always choose D (=defect)
<i>Unforgiving</i>	
Grim trigger	Cooperate until an opponent defects, and then switch to “always defect.”
Grim2-A	Cooperate until 2 opponents defect, and then switch to “always defect.”
Grim2-B	Cooperate until 2 opponents <i>consecutively</i> defect, and then switch to “always defect.”
Grim3-A	Cooperate until 3 opponents defect, and then switch to “always defect.”
Grim3-B	Cooperate until 3 opponents <i>consecutively</i> defect, and then switch to “always defect.”
<i>Forgiving</i>	
Tit for Tat (TFT)	Cooperate unless the previous opponent defected.
Two-tits-for-tat (2TFT)	Cooperate unless an opponent defected in <i>any</i> of the last 2 rounds (play D for two consecutive rounds after a defection is observed)
Tit-for-two-tats (TF2T)	Cooperate unless the opponents defected in <i>each</i> of the last 2 rounds.
Three-tits-for-tat (3TFT)	Cooperate unless an opponent defected in <i>any</i> of the last 3 rounds (play D for three consecutive rounds after a defection is observed)
Tit-for-three-tats (TF3T)	Cooperate unless the opponents defected in <i>each</i> of the last 3 rounds.

Table 3. Strategies considered

It is convenient to group the strategies listed in Table 3 into three distinct *strategy sets*. The first set includes strategies in which actions are *unconditional* on histories and prescribe the indefinite repetition of the same action in the prisoner’s dilemma: “always cooperate” and “always defect.” The remaining ten conditional strategies prescribe cooperation in the initial period. We divide them into two sets. One includes *unforgiving strategies*, in which one or more observed defections triggers a switch to a *permanent* punishment phase; it includes “grim trigger” and more lenient versions of such strategy in which the switch to the punishment phase is triggered only if more than one defection is observed (consecutively and not). The last strategy

set includes *forgiving* strategies, in which observed defections trigger a *temporary* punishment phase. It includes “tit for tat” and more lenient or less forgiving variants that have either a delay in triggering to the punishment phase or have a longer punishment phase. While “Always Defect” and “Grim Trigger” are equilibrium strategies, other strategies considered, such as “Always cooperate,” are clearly not.

We estimate the importance of each candidate strategy with a maximum likelihood approach, as in Dal Bó and Fréchette (2011) and Fudenberg et al. (2011). The estimation employs data from all cycles and presumes that (i) all subjects face the same probability distribution of adopting in a cycle one of the 12 strategies considered, (ii) subjects may change strategy from cycle to cycle (but not within a cycle), and (iii) subjects may make errors in implementing actions, i.e., with some probability (time-invariant, and identical across subjects) a subject may choose an action that is not recommended by the strategy adopted.⁶

In the PP treatment subjects could use personal punishment to immediately respond to an opponent’s action. We are especially interested in studying if and how subjects use personal punishment to complement or to substitute for sanctions based on defection. To this end, we have considered only strategies that condition on the outcome of the prisoner’s dilemma in the first stage of the game, but do not condition on histories of play from previous periods. For simplicity, we have included only strategies that prescribe personal punishment only if someone defected.⁷ Hence, we end up considering eight “punishment strategies” because personal punishment might be selected only in three possible outcomes of the prisoner’s dilemma: CD,

⁶ The estimation was executed adapting the code included in the supplementary material of Dal Bó and Fréchette (2011). The details of the estimation procedure are reported in Appendix A.

⁷ This is because in the PP treatment, individuals used personal punishment in less than 0.5% of the periods where CC was the outcome of the prisoner’s dilemma.

DC, and DD. The prevalence of each of these eight punishment strategies is estimated using the aforementioned maximum likelihood approach.

6 Results

This section presents a comparison of outcomes and strategies for different subject pools. The findings are organized into five main results. The first result concerns the differences in overall cooperation rates across treatments. The second illustrates the strategies adopted by the two subject pools in the treatments without personal punishment. The third and the fourth results describe students and workers' strategies in the treatments with personal punishment. Finally, the fifth result discusses subject-pool differences in the use of personal punishment.

Result 1. *Average cooperation rates are higher among students than workers in all treatments.*

Figure 1 and Table 4 provide support for Result 1. In the NP treatment the cooperation rate in all periods is 16.1 percentage points higher for students than for workers (Table 4, column 1; the difference is significant at the 5% level).⁸ This difference is confirmed by data from the first period of each cycle, which is 10.5 percentage points higher for students than for workers (Table 4, column 2; the difference is not significant).

A similar finding emerges from the PP treatment. Students' cooperation rate is 11.1 percentage points higher than workers' in all periods, and 11 percentage points when considering only the first period of each cycle. Differences are significant at the 5% and 1% levels,

⁸ For cycle $k=1, \dots, K$ of a session, define the action of subject $j=1, \dots, J$ in period $t=1, \dots, T^k$ as $a_{jt}^k=0,1$, where 1 is cooperation. The *cooperation rate of subject j* is $c_j = \sum_{k=1}^K \sum_{t=1}^{T^k} a_{jt}^k / \sum_{k=1}^K T^k$ between 0 and 1 (reported in %), and across subjects is $c = \sum_{j=1}^J c_j / J$. So, if cycles have different length T^k , then they receive different weight in the measure c of average cooperation.

respectively (Table 4, column 2).

Figure 1. Cooperation rates

Notes to Figure 1: NP= treatment without personal punishment; PP=treatment with personal punishment. Cooperation rates are calculated across all periods of all cycles, first by dividing the number of periods of all five cycles in which a subject cooperated by the total number of periods played, then taking the average across subjects. This implies that the weight of each cycle on the cooperation rate in a session is proportional to its length, but the sessions in the treatment are equally weighted.

	All periods	Periods 1
	Marginal effect	Marginal effect
	(s.e.)	(s.e.)
PP treatment	0.142** (0.055)	0.127 (0.102)
Worker × NP treatment	-0.164** (0.053)	-0.092 (0.094)
Worker × PP treatment	-0.125** (0.041)	-0.127*** (0.047)
Constant	0.570*** (0.046)	---
Observations	800	800
R-squared	0.091	---
Pseudo-R squared	---	0.027

Table 4. Initial and average cooperation rates

Notes to Table 4: The first column reports the marginal effects obtained by a logit regression where the dependent variable is the binary decision to cooperate (=1) or defect (=0) in period 1 of each cycle. The second column reports the estimated coefficients from an OLS regression in which the dependent variable is the average cooperation rate for each individual (i.e., for each subject in a cycle). In this second regression, each observation is weighted for the length of the cycle it belongs to, so cycles with longer length have more weight. In both regressions, we include three independent variables, which capture treatment effects. The first regressor is a dummy that takes value 1 in the treatment with Personal Punishment and zero otherwise. The second and third regressors interact the dummy “worker” (taking value 1 for subjects who are not undergraduate students, zero otherwise) with the two dummies for the NP and PP treatment. These last two regressors capture the difference in average cooperation rates between students and workers, in the distinct cases with and without personal punishment. In parentheses we report standard errors robust for clustering at the session level: * significant at 10%; ** significant at 5%; *** significant at 1%.

Result 2. *In the treatment without personal punishment, students and workers differ in their strategy adoption. Workers select “always defect” more frequently than students, and select “forgiving” strategies less frequently.*

Support for Result 2 comes from Table 5, which reports the maximum likelihood estimates of the population proportions for each of the 12 strategies considered.

Strategy	Students		Workers	
	Coefficient	s.e.	Coefficient	s.e.
<i>Unconditional</i>				
Always cooperate	0.177 ***	0.039	0.164 ***	0.024
Always Defect	0.238 ***	0.060	0.366 ***	0.051
<i>Unforgiving</i>				
Grim trigger	0.061 **	0.025	0.101 *	0.052
Grim2-A	0.021 *	0.012	0.088 ***	0.031
Grim2-B	0.060 **	0.024	0.000	0.015
Grim3-A	0.049 ***	0.018	0.000	0.000
Grim3-B	0.099 ***	0.023	0.083 **	0.033
<i>Forgiving</i>

Table 5. Maximum Likelihood Estimation of strategy adoption (NP treatment)

The estimated shares of “always defect” are 23.8% for students and 36.6% for workers; the shares of “forgiving” strategies are 29.6% for students and 19.7% for workers.

Table 5 also reports the estimate for the parameter γ , which controls the variance of the distribution of errors in implementing the action prescribed by the strategy selected. This variance is higher among workers than students, which suggests that it is more difficult to capture workers' behavior through the set of strategies considered.

Result 3: *In the treatment with personal punishment, students cooperate more than in the treatment without. When personal punishment is available, students adopt conditionally cooperative strategies more frequently and “always defect” less frequently.*

The cooperation rate in periods 1 for students significantly increases from 73.5 in the NP treatment to 84.5 in the PP treatment (Figure 1, Table 4), as already noted in Camera and Casari (2009). The maximum likelihood estimation of strategies helps understanding why this is so, as it describes a substantial change in the strategies adopted. Recall that the strategies estimated in Table 5 explicitly focus on patterns of behavior in the prisoners' dilemma and do not condition on personal punishment; the use of personal punishment is analyzed later. Students are less likely to adopt unconditional strategies when personal punishment is available; the estimated share of “always cooperate” drops a few points, while the estimated share of “always defect” dramatically drops from 23.8% to 7.8% (see Table 5 vs. Table 6). The data show a substantial increase both in the share of “unforgiving” strategies (from 29% to 38.4%) and in the share of “forgiving” strategies (from 29.6% to 41.8%). The availability of personal punishment seems to motivate students to make an attempt at coordinating on cooperation. This is done by adopting strategies that start with cooperation, and prescribe a switch to a punishment phase only after one or more defections are observed.

Interestingly, the increase in cooperation rates is associated with the adoption of conditional

rather than unconditional cooperative strategies. One could have conjectured that what sustained high cooperation in the PP treatment was the “always cooperate” strategy together with the use of personal punishment targeted to defectors. The estimation of individual strategies adopted by students provides no support for this conjecture. As shown below, the data exhibit different patterns for workers.

strategy	Students		Workers

Table 6. Maximum Likelihood Estimation of strategy adoption (PP treatment).

Result 4: *In the treatment with personal punishment, workers cooperate more than in the treatment without. When personal punishment is available, workers follow “always cooperate” more frequently and “always defect” less frequently.*

The cooperation rate in period 1 for workers increases from 63% in the NP treatment to 73.5% in the PP treatment (Figure 1). The impact on overall cooperation rates of the availability of personal punishment is similar across subject pools. However, the impact on strategy adoption is qualitatively different.

Workers are less likely to adopt “always defect” and more likely to adopt “always cooperate” when personal punishment is available (see Table 5 vs. Table 6). The estimated shares drop from 36.6% to 25.4% for “always defect” and increase from 16.4% to 26.4% for “always cooperate.” The changes are approximately of the same magnitude, and minimal variations appear for “Forgiving” and “Unforgiving” strategies. Comparing Tables 5 and 6 suggests that, in the case of workers, the availability of personal punishment options raises by about 10 percentage points the prevalence of “always cooperate” while decreasing the prevalence of “always defect” by the same amount. One interpretation is that workers substituted the cooperative for the uncooperative unconditional strategy.

Result 5: *Workers used personal punishment less frequently than students.*

The support for Result 5 is in Table 7, which reports results for a maximum likelihood estimation of the prevalence of the eight personal punishment strategies considered, separated by subject pool. In the experiment, the strategy that prescribes to never use personal punishment (“never punish”) has a 62.8% share among workers and 44.1% among students. In both subject pools personal punishment is used basically only to sanction a defection of the opponent. The strategy that prescribes personal punishment only when the subject cooperated and the opponent defected (“punish cheaters”), is more widely adopted among students than workers (38.7% among students vs. 21.9% among workers). The share of students and workers who punish a defector when they have *also* defected is, instead, identical (“punish all defections”).

Given our previous Results 3 and 4, we can interpret this finding as an indication that the availability of personal punishment has a different impact on the way students and workers police deviations from cooperation. Students use *personal* punishment as a tool that

complements *decentralized* punishment. Relative to the NP treatment, in the PP treatment students are more likely to adopt strategies that trigger a decentralized punishment phase (when a defection is observed) and *also* use personal punishment on defectors. Instead, workers are more likely to adopt unconditional cooperative strategies in the PP than in the NP treatment, sanctioning defections with personal punishment rather than with decentralized punishment.

Personal punishment strategy	Students		Workers	
	Coefficient	s.e.	Coefficient	s.e.
Never punish (000)	0.441 ***	0.064	0.628 ***	0.110
Punish cheaters (100)	0.387 ***	0.062	0.219 ***	0.079

Log-likelihood	748.661		646.876	
N	200		200	

Table 7. Maximum Likelihood Estimation on punishment strategies adoption

Notes to Table 7: Punishment strategies are coded as follows: 0 means “do not punish” 1 means “punish”. The first digit of the strategy is the action to be taken when the subject cooperates and the opponent defects. The second indicates the action to be taken when the subject defects and the opponent cooperates. The third indicates the action to be taken when the subject defects and the opponent defects.

7 Conclusions

This paper reports results from an experiment on social dilemmas involving a pool of college students and one of clerical workers. It contributes to the literature on cooperation in two ways. First, a methodological contribution is associated to the discovery of differences in behavior across subject pools. Most of the existing laboratory studies on this topic have been conducted with college students as subjects. The data show that not all results from student subjects can be generalized. Workers in our experiment tended to cooperate with a lower frequency overall and to start defecting from the beginning of the game. In contrast, previous studies have found that students are on average less cooperative than other subject pools. There may be a variety of

possible explanations. On the one hand, clerical workers may be a peculiar sample that is different from other samples of adult population. Perhaps, these differences originate in a stronger orientation toward individual tasks that characterize clerical work. This may feed back in clerical workers' ability to coordinate with others on cooperative tasks. On the other hand, social dilemmas with known, deterministic duration may simply induce qualitatively different behavior than when duration is indefinite, as in our experiment.

A second contribution of the paper emerges from comparing individual strategy adoption in the prisoner's dilemma, in treatments with and without a personal punishment opportunity. Workers were more likely to unconditionally cooperate in treatments with personal punishment than without. Instead, the introduction of personal punishment made students more likely to adopt a cooperative strategy based on the threat of temporary punishment, i.e., to adopt "forgiving" strategies.

In the treatment with a personal punishment opportunity, there are additional remarkable differences between students and workers. Students no longer followed "always defect," while the prevalence of this uncooperative behavior among workers, albeit lower, remained strong. In general, in the experiment personal punishment is either not used or it is used to sanction defectors. There was virtually no anti-social punishment both among students and workers, i.e., defectors did not punish cooperators. The one difference is that workers were overall less likely than students to use personal punishment.

These findings show that, when faced with a cooperative task, dissimilar subject pools exhibit substantially different strategy profiles. In particular, we observe two disparities. One the one hand workers were less prone to adopt cooperative strategies. Even in treatments with personal punishment, no less than one fourth of workers started by defecting and continued

defecting unconditionally. On the other hand, workers were overall less inclined to follow strategies that sanction uncooperative behavior either with decentralized punishment or with personal punishment. These two findings may explain why we observed less cooperation among workers than students.

Appendix A

Strategy estimation procedure

To estimate the prevalence of each strategy in our dataset we use a standard maximum likelihood (ML) procedure, as in Dal Bó and Frechette (2011) and Fudenberg et al. (2011). There are two basic assumptions. First, each subject $j = 1, \dots, J$ (where $J = 40$ in each of our four treatments) adopts the same strategy $k \in K$ in all periods of a cycle $n = 1, \dots, 5$. Subject j may choose a different strategy in different cycles, unlike in Dal Bó and Frechette (2011) and Fudenberg et al. (2011). Therefore, we denote by $i \in I := \{1, \dots, 5J\}$ the *individual*, i.e., a subject in a cycle. The individual is our unit of observation. Second, in every period, individual i may make a mistake in choosing the action prescribed by the strategy adopted. This mistake is distributed identically and independently across individuals and periods.

More specifically, consider individual i in period $t = 1, \dots, T^i$, where T^i is individual-specific because cycles have generally different durations. Let $s_t^i(k) = -1, 1$ denote the choice of individual i in period t if she follows strategy k ; -1 indicates that D should be implemented, and 1 indicates C . It is assumed that individual i chooses C if $y_t^i = 1$ and chooses D otherwise, where we define

$$y_t^i := \begin{cases} 1 & \text{if } s_t^i(k) + \gamma \varepsilon_t^i \geq 0 \\ 0 & \text{otherwise.} \end{cases}$$

Here ε_t^i is an error term with probability density function such that the likelihood $P^i(k)$ that individual i adopts strategy k has a logistic distribution. The parameter γ controls

the variance of the error. Consequently, $\frac{1}{1 + e^{-1/\gamma}}$ is the probability that the action implemented by an individual in any period coincides with the actions prescribed by the strategy. Hence, the likelihood that individual i adopts strategy k is

$$P^i(k) = \prod_{t=1}^{T^i} \left(\frac{1}{1 + \exp(-s_t^i(k)/\gamma)} \right)^{y_t^i} \left(\frac{1}{1 + \exp(s_t^i(k)/\gamma)} \right)^{1-y_t^i}.$$

The function we wish to maximize is the log-likelihood

$$\sum_{i \in I} \ln \left(\sum_{k \in K} \pi_k P^i(k) \right). \quad (1)$$

We estimate the parameter vector $\pi := (\pi_k)_{k \in K}$ and the variance parameter γ that maximize (1). The vector π describes the probability distribution over the set K of strategies. The estimated parameter $\hat{\pi}_k \in \hat{\pi}$, represents the proportion of individuals (or observations) that is attributed to strategy k , or, equivalently, the prevalence of each strategy in our dataset. The estimated parameter $\hat{\gamma}$ provides a measure of the probability of mistakes.

Appendix B—Not for Publication

Instructions for the NP treatment without personal punishment

Overview

This is an experiment in decision-making. Purdue University has provided funds for this research. The instructions are simple. If you follow them carefully and make good decisions, you can earn an appreciable amount of money. These earnings will be paid to you in cash at the end of the experiment.

We ask that you not talk with one another for the duration of the experiment. Please turn off your cell-phones. Do not use e-mail.

During the course of this experiment, you will be called upon to make decisions in several periods. The experiment is divided into **five** sequences of periods and each sequence is referred to as a **cycle**.

- At the beginning of a cycle, each participant in this room will be randomly assigned to a **set**.
- In each set there will be **four** persons.
- For the whole duration of a cycle, you will interact exclusively with the three other participants in that set and nobody else.
- You will never meet again these participants in the following cycles.

In each **period** of a cycle:

- In each period you will be matched to one other participant selected at random from the set you are assigned to. We will refer to this person as “**your match**.”
- You will not be informed of the identity of your match. Hence, you do not know when you have already interacted with that person in previous periods of the same cycle.
- You and your match will interact according to the rules described in the upper portion of your screen. The rules will be explained in a moment.

- After each period you will be re-matched to a participant chosen at random from the set you are assigned to. There is one chance out of three that you will be matched with any given person in your set.

The screenshot shows a game interface with several key elements:

- Period:** A box labeled "Period" points to the top left of the screen, which displays "Period: 2" and "Your ID: 18".
- Your matches' choice:** A box labeled "Your matches' choice" points to the top right of the screen, which shows a choice between "Y" and "Z".
- Your Choice:** A box labeled "Your Choice" points to the left side of the screen, which shows a choice between "Y" and "Z".
- Payoff Table:** A 2x2 grid of boxes shows the payoffs for each combination of choices:

Y	You get 25, The other gets 25	You get 5, The other gets 30
Z	You get 30, The other gets 5	You get 10, The other gets 10
- Choice Input:** A box labeled "You ignore the ID of your match" points to the "Please enter your choice" section, which has radio buttons for "Y" and "Z" and a "Submit" button.
- Summary of Results:** A box labeled "Your set" points to the "Summary of Results in cycle 1" section, which lists "Persons in your set: ID18(you), ID20, ID17, ID19".
- History of Choices:** A box labeled "History of choices of your previous matches" points to a table below the summary, which has a column for "Your match" circled in red.

Period	ID18	Your match	Other person	Other person	Your match ID	Your earnings
1	Y	Z	unknown	unknown	unknown	5

Interaction rules

In a period you and your match can make either of two choices, Y or Z. The points you earn in a period depend upon both the choice you make and the choice made by your match in that period. As the payoff table on your screen (above) indicates, there are four possible outcomes:

1. If both of you choose Y this period then: you both earn **25** points.
2. If you choose Y this period and your match chooses Z then: you earn **5** points and your match earns **30** points.
3. If you choose Z this period and your match chooses Y then: you earn **30** points and your match earns **5** points.

4. If you both choose Z then: you both earn **10** points.

To make your choice in each period, click the button next to either Y or Z. You may change your mind at any time prior to clicking the “Submit” button by simply clicking on the button next to Y or Z. You are free to choose Y or Z in every period. When you are satisfied with your choice, click the “Submit” button. After all persons have made their choices, the results of the period will appear on your screen.

The screenshot shows a game interface with a light beige background. At the top, a box labeled "Your results" has an arrow pointing to the "Period 3 Results" section. Below this, a box labeled "Random number" has an arrow pointing to a large number "3". The "Period 3 Results" section displays: "Your Choice: Y", "Your matches' choice: Z", and "Your period earnings: 5". Below this is a "Continue" button. At the bottom, a "Summary of Results in cycle 1" table is shown, listing results for three periods. The table has columns for Period, ID1, Your match, Other person, Other person, Your match ID, and Your earnings.

Period	ID1	Your match	Other person	Other person	Your match ID	Your earnings
1	Z	Z	unknown	unknown	unknown	10
2	Y	Y	unknown	unknown	unknown	25
3	Y	Z	unknown	unknown	unknown	5

The result screen (above) will display the number of points you have earned for the period along with **your choice and the choice of your match**. The first column of the ‘Summary of Results’ table contains your past choices. The second column concerns the choices of your previous matches. Notice that **choices in the second column were most likely made by different persons in different periods. You are not given information on the choices made by the other two persons in your set**. Please record your results for the period on your RECORD SHEET under the appropriate headings.

At this stage a ball will be drawn from an urn containing one hundred balls numbered from 1 to 100. Each ball is equally likely to be selected. The computer program will randomly draw a ball and show the number on the result screen (above). If this random number is less than or equal to 95, then the cycle will continue into the next period. If this number is greater than 95, then the cycle ends. Therefore, **after each period there is a 95% chance that there will be another period of interactions in the cycle and a 5% chance that the cycle will end.**

Suppose that a number less than or equal to 95 has been drawn. Then you press the “Continue” button to proceed. You will face the same decisional situation as in the previous period, but **with a person selected at random from the set of participants you were assigned to.** Remember that there are four participants in each set.

Before making your choice, you may review all the outcomes in previous periods of the cycle by scrolling down the “Summary of Results” table. The table shows your history and the past choices of the persons who happened to be your match in the period. You then choose either Y or Z. Your choice and the choice of your match this period are recorded and added to the Summary of Results table in the lower portion of your screen. You record the outcome and your point earnings for the period.

If the number drawn is greater than 95 then the cycle ends. When a cycle ends, you will be notified in a new screen. There will be a total of five cycles. The rules in the following cycles are the same as in the first, but you will interact with different persons. More precisely, after each cycle, new sets of persons will be formed. This assignment does not depend on actual choices. **A participant will never interact with a person for more than one cycle.**

Earnings

The points you earned in each period are added up. For every 10 points that you earn you will receive 13 cents (\$.13). Therefore, the more points you earn the more money you earn. In addition, you will receive a \$10 show-up fee. You will be paid your earnings in cash and in private at the end of today’s session.

Final Comments

First, do not discuss your choices or your results with anyone at any time during the experiment.

Second, your ID# is private. Do not reveal it to anyone.

Third, since there is a 95% chance that at the end of a period the cycle will continue, you can expect, on average, to interact for 20 periods in a given cycle. However, since the stopping decision is made randomly, some cycles may be much longer than 20 periods and some others may be much shorter.

Fourth, remember that after each period you will be matched randomly to someone in the set you were assigned to. As there are four people in the set, the probability of you being matched with the same person in two consecutive periods of a cycle is $1/3$. You are not told the identity of your match.

Fifth, the rules are the same in all five cycles. After a cycle, you will never meet again the same participants.

Questions?

Now is the time for questions. Does anyone have any questions before we begin?

Instructions for the PP treatment with personal punishment

Overview

This is an experiment in decision-making. Purdue University has provided funds for this research. The instructions are simple. If you follow them carefully and make good decisions, you can earn an appreciable amount of money. These earnings will be paid to you in cash at the end of the experiment.

We ask that you not talk with one another for the duration of the experiment. Please turn off your cell-phones. Do not use e-mail.

During the course of this experiment, you will be called upon to make decisions in several periods. The experiment is divided into **five** sequences of periods and each sequence is referred to as a **cycle**.

- At the beginning of a cycle, each participant in this room will be randomly assigned to a **set**.
- In each set there will be **four** persons.
- For the whole duration of a cycle, you will interact exclusively with the three other participants in that set and nobody else.
- You will never meet again these participants in the following cycles.

In each **period** of a cycle:

- In each period you will be matched to one other participant selected at random from the set you are assigned to. We will refer to this person as “**your match**.”
- You will not be informed of the identity of your match. Hence, you do not know when you have already interacted with that person in previous periods of the same cycle.
- You and your match will interact according to the rules described in the upper portion of your screen. The rules will be explained in a moment.
- After each period you will be re-matched to a participant chosen at random from the set you are assigned to. There is one chance out of three that you will be matched with any given person in your set.

Summary of Results in cycle 1

Persons in your set: ID2 (you), ID3, ID1, ID4

Period	ID2	Your match	Other person	Other person	Reduction received	Your match ID	Your earnings
1	Z	Y	unknown	unknown	No	unknown	30
2	Z	Z	unknown	unknown	Yes	unknown	0

Interaction rules

Each period is divided into two stages. In stage 1 you and your match can make either of two choices, Y or Z. The points you earn depend upon both the choice you make and the choice made by your match in that period. As the payoff table on your screen (above) indicates, there are four possible outcomes for stage 1:

1. If both of you choose Y this period then: you both earn **25** points.
2. If you choose Y this period and your match chooses Z then: you earn **5** points and your match earns **30** points.
3. If you choose Z this period and your match chooses Y then: you earn **30** points and your match earns **5** points.
4. If you both choose Z then: you both earn **10** points.

To make your choice in stage 1, click the button next to either Y or Z. You may change your mind at any time prior to clicking the “Submit” button by simply clicking on the button next to Y or Z. You are free to choose Y or Z in every period. When you are satisfied with your choice, click the “Submit” button. After all persons have made their choices, the results of stage 1 will appear on your screen (below).

The screenshot shows a game interface with a light beige background. At the top, it says "Period 1" and "Results stage 1". Below this, there is a table of results:

Your choice	Z
Choice of your match	Z
Your phase 1 earnings	10

Below the table, it says "Stage 2" and "Would you like to lower the earnings of your match?". There are two radio buttons: "No" (selected) and "Yes". At the bottom center, there is a red "Submit" button.

Before moving to another period, you have the opportunity to pay a cost to lower the earnings of your match (stage 2). You can click the button next to either NO or YES and then click submit when satisfied with your choice.

If you choose NO, no points will be subtracted from the earnings of your match.

If you choose YES, 5 points will be subtracted from your earnings and 10 points will be subtracted from the earnings of your match.

After all persons have made their choices for stage 2, the final results of the period will appear on the lower portion of your screen (see screen below). Please notice that your period earnings can be negative. If your earnings in the period are negative, they will reduce your cumulative earnings.

The screenshot shows a game result screen. On the left, two white boxes with black borders contain the text "Your results" and "Random number". Arrows point from these boxes to the corresponding elements on the screen. The "Your results" box points to a list of results under the heading "Period 2 Results". The "Random number" box points to a large, bold number "3". Below the results is a "Continue" button and a "Summary of Results in cycle 1" table.

- Your choice: Z
- Your matches' choice: Z
- Your phase 1 earnings: 10
- Cost for your second stage request: 0
- Earnings reduction received in second stage: -10
- Your period earnings: 0

The cycle: will continue

Summary of Results in cycle 1

Period	ID2	Your match	Other person	Other person	Reduction received	Your match ID	Your earnings
1	Z	Y	unknown	unknown	No	unknown	30
2	Z	Z	unknown	unknown	Yes	unknown	0

The result screen (above) will display the number of points you have earned for the period along with **your choices and the choices of your match** for both stage 1 and stage 2. The first column of the ‘Summary of Results’ table contains your past choices in stage 1. The second column concerns the choices in stage 1 of your previous matches. Notice that **choices in the second column were most likely made by different persons in different periods. You are not given information on the choices made by the other two persons in your set.** One of the columns lists the “Reduction received” in each period. It is marked “Yes” when your match requested to lower your earning and “No” otherwise. Please record your results for the period on your RECORD SHEET under the appropriate headings.

At this stage a ball will be drawn from an urn containing one hundred balls numbered from 1 to 100. Each ball is equally likely to be selected. The computer program will randomly draw a ball and show the number on the result screen (above). If this random number is less than or equal to 95, then the cycle will continue into the next period. If this number is greater than 95, then the cycle ends. Therefore, **after each period there is a 95% chance that there will be another period of interactions in the cycle and a 5% chance that the cycle will end.**

Suppose that a number less than or equal to 95 has been drawn. Then you press the “Continue” button to proceed. You will face the same decisional situation as in the previous period, but **with a person selected at random from the set of participants you were assigned to**. Remember that there are four participants in each set.

Before making your choice, you may review all the outcomes in previous periods of the cycle by scrolling down the “Summary of Results” table. The table shows your history and the past choices of the persons who happened to be your match in the period. You then choose either Y or Z in stage 1 and NO or YES in stage 2. Your choice and the choices of your match this period are recorded and added to the Summary of Results table in the lower portion of your screen. You record the outcome and your point earnings for the period.

If the number drawn is greater than 95 then the cycle ends. When a cycle ends, you will be notified in a new screen. There will be a total of five cycles. The rules in the following cycles are the same as in the first, but you will interact with different persons. More precisely, after each cycle, new sets of persons will be formed. This assignment does not depend on actual choices. **A participant will never interact with a person for more than one cycle.**

Earnings

The points you earned in each period are added up. For every 10 points that you earn you will receive 13 cents (\$.13). Therefore, the more points you earn the more money you earn. In addition, you will receive a \$5 show-up fee. You will be paid your earnings in cash and in private at the end of today’s session.

Final Comments

First, do not discuss your choices or your results with anyone at any time during the experiment.

Second, your ID# is private. Do not reveal it to anyone.

Third, since there is a 95% chance that at the end of a period the cycle will continue, you can expect, on average, to interact for 20 periods in a given cycle. However, since the stopping decision is made randomly, some cycles may be much longer than 20 periods and some others may be much shorter.

Fourth, remember that after each period you will be matched randomly to someone in the set you were assigned to. As there are four people in the set, the probability of you being matched with the same person in two consecutive periods of a cycle is $1/3$. You are not told the identity of your match.

Fifth, the rules are the same in all five cycles. After a cycle, you will never meet again the same participants.

Questions?

Now is the time for questions. Does anyone have any questions before we begin?

QUIZ

1. The total number of **cycles** is _____
2. You are at the beginning of the cycle. How many **periods** do you expect the cycle will last, on average? _____
3. You are in period 15 of the cycle. How many additional **periods** do you expect, on average? _____
4. The number of **participants** in the experiment (total in the room) is _____
5. In a given **cycle** with how many participants could you interact with (i.e. number of people in a set)? _____
6. In a given **period** with how many participants do you interact with? _____
7. Other than your match, will you know at the end of the period the actions taken by people **in your set**? _____
8. Will you know at the end of the period the actions taken by participants **outside your set**? _____
9. Before choosing an action, will you know the **ID** of your match? _____
10. If ID 5 is in your set this cycle, is there any chance that ID 5 will be your match in future cycles? _____
11. How many points do you earn if both you and your match choose **Y**? _____
12. If the experiment lasts 100 periods and everybody always chooses **Y**, how many dollars are your going to earn? _____
13. How many points do you earn if you and your match choose **Z**? _____
14. If the experiment lasts 100 periods and everybody always chooses **Z**, how many dollars are your going to earn? _____
