Abstract

We extend the available asymptotic theory for autoregressive sieve estimators to cover the case of stationary and invertible linear processes driven by independent identically distributed (i.i.d.) infinite variance (IV) innovations. We show that the ordinary least squares sieve estimates, together with estimates of the impulse responses derived from these, obtained from an autoregression whose order is an increasing function of the sample size, are consistent and exhibit asymptotic properties analogous to those which obtain for a finite-order autoregressive process driven by i.i.d. \sim IV errors. As these limit distributions cannot be directly employed for inference because they either may not exist or, where they do, depend on unknown parameters, a second contribution of the paper is to investigate the usefulness of bootstrap methods in this setting. Focusing on three sieve bootstraps: the wild and permutation bootstraps, and a hybrid of the two, we show that, in contrast to the case of finite variance innovations, the wild bootstrap requires an infeasible correction to be consistent, whereas the other two bootstrap schemes are shown to be consistent (the hybrid for symmetrically distributed innovations) under general conditions.

Keywords: Infinite variance; linear process; sieve estimator; wild bootstrap; permutation bootstrap.

1 INTRODUCTION

A large body of statistical literature exists around the related inference problems of consistent parameter estimation and hypothesis testing within autoregressive and moving average models of (potentially) infinite orders. Key applications include: (i) estimation of the (scale free) spectral density, (ii) inference on impulse response functions, (iii) lag length selection in autoregressive specifications and (sieve) approximations, (iv) point and interval forecasts. Following the pioneering work of Berk (1974), the majority of this literature has been articulated in the familiar L_2 norm and is therefore not applicable in the case of time series driven by innovations which display infinite variance (IV). Such heavy tailed data are widely encountered in many areas of application including financial, insurance, macroeconomic, actuarial, telecommunication network traffic, and meteorological time series; see, *inter alia*, Embrechts *et al* (1997), Resnick (1997), Finkenstädt and Rootzén (2003) and Davis (2010).

The extension of these time series methods to the case of IV innovations is particularly challenging for at least two distinct reasons. First, under IV the asymptotic distributions of estimators and statistics obtained from autoregressive and moving average time series models are in general non-standard (in particular, they depend on unknown nuisance parameters, such as the so-called ‘tail index’, see e.g. Davis and Resnick, 1985a). Second, the bootstrap techniques which are frequently used to approximate the asymptotic distributions of these quantities in the finite-variance case, tend not to be robust to infinite second order moments and require some modification. This is due to the fact that the bootstrap distributions are dominated by sample extremes (Athreya, 1987; Knight, 1989).

In the finite-variance case, sieve-based inference on linear stationary processes is well-understood and is based on fitting an autoregressive approximation whose order increases with the sample size. Berk (1974) and Lewis and Reinsel (1985) study the asymptotic distributions of the resulting sieve OLS estimators for univariate and multivariate processes, respectively, while Kreiss (1997) and Paparoditis (1996) demonstrate the asymptotic validity of the associated standard i.i.d. and wild bootstrap sieve inference procedures. In this paper we explore asymptotic and bootstrap sieve-based methods of inference for stationary linear processes driven by IV innovations, restricting our attention to ordinary least squares (OLS) estimators. While other estimators, including M estimators (see, *inter alia*, Knight 1987, and Davis *et al.*, 1992), and estimators based on trimmed data (Hill, 2013, and references therein) can be more efficient than OLS (most notably where the tail index is considerably below 2; see Calder and Davis, 1998), these estimators are dominated by OLS in the finite variance case; see Maronna *et al.* (2006,p.269) for a comparison of M and OLS estimators. Importantly, OLS remains widely used by applied workers, especially in economics and finance, and part of our contribution is to show how the small sample efficacy of OLS-based methods can be considerably improved when the innovations are IV using bootstrap methods.

For finite-order autoregression driven by i.i.d. IV errors, it has been established that the OLS estimators of the autoregressive parameters are consistent but that three possible types of asymptotic behavior can occur; see, *inter alia*, Hannan and Kanter (1977) and Davis and Resnick (1985b, 1986). To illustrate this via a simple example, consider the AR(1) process

$$X_t = \beta X_{t-1} + \varepsilon_t, \quad t \in \mathbb{Z},$$

where $|\beta| < 1$ and ε_t are symmetric i.i.d. in the domain of attraction of an α -stable distribution (defined formally in section 2) with tail index $\alpha \in (0, 2)$. The large sample behavior of the OLS estimate of β , denoted $\hat{\beta}$, depends on the *unknown* distribution of $\{\varepsilon_t\}$. In particular, three possible cases arise:

CASE (i): If $\mathbf{E}|\varepsilon_1|^\alpha = \infty$, then there exists a sequence l_T , slowly varying at infinity

and depending on the distribution of ε_t , such that

$$l_T T^{1/\alpha}(\hat{\beta} - \beta) \xrightarrow{w} \frac{1 - \beta^2}{(1 - \beta^\alpha)^{1/\alpha}} \frac{S_1}{S_0}, \quad (1)$$

where S_1 and S_0 are independent α and $\alpha/2$ -stable random variables (r.v.'s), respectively; see Davis and Resnick (1986, p.557);

CASE (ii): If $\mathbf{E}|\varepsilon_1|^\alpha < \infty$ and $\lim_{t \rightarrow \infty} P(|\varepsilon_1 \varepsilon_2| > t)/P(|\varepsilon_1| > t) = 2 \mathbf{E}|\varepsilon_1|^\alpha$, then there exists a slowly varying sequence l_T such that (1) holds but where S_1 and S_0 are now dependent α and $\alpha/2$ -stable r.v.'s; see Davis and Resnick (1985b, p.279);

CASE (iii): If $\mathbf{E}|\varepsilon_1|^\alpha < \infty$ and $\lim_{t \rightarrow \infty} P(|\varepsilon_1 \varepsilon_2| > t)/P(|\varepsilon_1| > t) = \infty$ (note that there are no other possible values for this limit than $2 \mathbf{E}|\varepsilon_1|^\alpha$ and ∞), then $\hat{\beta} - \beta$ cannot be normalised such that a non-degenerate limiting distribution obtains; see Davis and Resnick (1985b).

Our first contribution is to show that this asymptotic trichotomy carries over to the general IV linear process case, thereby extending the range of available asymptotic theory for OLS sieve estimators to cover the case of i.i.d. IV innovations. In doing so we establish the consistency of the OLS sieve estimators and the rates at which the order of the autoregressive approximation must increase with the sample size for these results to hold. We also use these results to demonstrate the consistency of two important estimators derived from the OLS sieve-based estimates, namely estimates of the impulse responses and of the scale-free spectral density function.

As the example above demonstrates, even with knowledge of the tail index, α , asymptotic inference based on the OLS sieve estimator may not be possible and, if it is, it will not be known which form of the asymptotic distribution should be used. Our second contribution is then to investigate the usefulness of bootstrap approximations to the distribution of the OLS sieve estimators in the IV case, complementing the recent work of Kreiss *et al.* (2011) who highlight the wide range of validity of autoregressive sieve bootstrap methods for the case of finite-variance data.

Whilst standard i.i.d. bootstrap methods are inconsistent in the IV case, other bootstrap methods can yield consistent inference for the case of the location parameter; these include the ‘ m out of n ’ bootstrap (Arcones and Giné, 1989), a parametric bootstrap (Cornea-Madeira and Davidson, 2015), the permutation bootstrap (LePage and Podgorski, 1996) and the wild bootstrap (Cavaliere *et al.*, 2013). Of these, the latter two preserve the sample extremes (even asymptotically) and are therefore anticipated to lead to more concentrated reference distributions than the unconditional distribution estimated by the ‘ m out of n ’ and parametric bootstraps (see the numerical evidence in LePage, 1992), and hence to deliver more powerful bootstrap tests. Moreover, issues surrounding sample length selection with the ‘ m out of n ’ bootstrap and preliminary estimation of the tail index and the asymmetry parameter with the parametric bootstrap are avoided. For these reasons, our focus will be on the permutation bootstrap, the wild bootstrap and a hybrid combination of the two.

In the context of the present problem, with the existence of asymptotic distributions not guaranteed in case (iii) above, we discuss consistency in terms of the proximity between some conditional finite-sample distributions of the OLS sieve estimate and their bootstrap counterparts. We show that the permutation and hybrid bootstraps are consistent under general conditions (the latter provided the innovations are symmetric), but that, in contrast to the case of finite variance innovations, the wild bootstrap is inconsistent unless an *infeasible* correction term is added to the difference between the original and bootstrap sieve estimates. Monte Carlo simulation results are presented which suggest that the permutation and hybrid

bootstraps outperform the uncorrected wild bootstrap, ‘ m out of n ’ bootstrap and i.i.d. bootstrap procedures in terms of finite sample size properties (and the latter two, also in terms of power). These results, consistent with the findings of LePage (1992) and Cavaliere *et al.* (2013) for the location testing problem, also show that the permutation, wild and hybrid bootstrap methods can lead to considerable gains in the finite-sample precision of OLS-based inference under IV, especially when the tail index is small, yet retain the superior properties of OLS-based inference when the innovations have finite variance.

The plan of the paper is as follows. In section 2 we detail our reference data generating process (DGP) and introduce the autoregressive sieve approximation, and associated OLS sieve estimators. In section 3 we establish the large sample properties of these estimators. Section 4 investigates the use of sieve bootstrap methods. Results from a Monte Carlo study are reported in section 5. An application to impulse response functions is offered in section 6. Main proofs are contained in section 7; additional theory and proofs are reported in Appendix A.1.

2 THE DGP AND SIEVE APPROXIMATION

Suppose that

$$X_t = \sum_{i=0}^{\infty} \gamma_i \varepsilon_{t-i}, \quad t \in \mathbb{Z}, \quad (2)$$

is a stationary and invertible linear process with IV innovations. Specifically, the following set of conditions is taken to hold.

ASSUMPTION 1

- (a) *The random variables ε_t ($t \in \mathbb{Z}$) form an i.i.d. sequence which is in the domain of attraction of an α -stable law, $\alpha \in (0, 2)$; i.e., the tails of the distribution of ε_t exhibit the power law decay, $P(|\varepsilon_t| > x) = x^{-\alpha} L(x)$, for $x > 0$, with $L(\cdot)$ a slowly varying function at infinity, and $\lim_{x \rightarrow \infty} P(\varepsilon_t > x)/P(|\varepsilon_t| > x) =: p \in [0, 1]$, $\lim_{x \rightarrow \infty} P(\varepsilon_t < -x)/P(|\varepsilon_t| > x) = 1 - p$. If $E|\varepsilon_1| < \infty$, it is assumed that $E\varepsilon_1 = 0$.*
- (b) *There exists a $\delta \in (0, \alpha) \cap [0, 1]$ such that $\sum_{i=0}^{\infty} i|\gamma_i|^{\delta/2} < \infty$.*
- (c) *The power series $\gamma(z) := \sum_{i=0}^{\infty} \gamma_i z^i$, where we set $\gamma_0 = 1$ with no loss of generality, has no roots on the closed complex unit disk.*
- (d) *Its reciprocal $1 - \sum_{i=1}^{\infty} \beta_i z^i := (\sum_{i=0}^{\infty} \gamma_i z^i)^{-1}$ satisfies $\sum_{i=0}^{\infty} |\beta_i|^{\delta} < \infty$, where δ is as defined in (b).*

REMARK 2.1. (i) The parameter α in part (a) of Assumption 1, which will be treated as unknown in this paper, controls the thickness of the tails of the distribution of ε_t , and, as such, is often referred to as the tail index, index of stability or characteristic exponent; see e.g. Chapter XVII of Feller (1971). Moments $E|\varepsilon_t|^r$ are finite for $r < \alpha$ and infinite for $r > \alpha$; the moment $E|\varepsilon_t|^\alpha$ can be either finite or infinite, discriminating between some results in section 3. The tail index is inherited by the limiting distribution of the appropriately normalized (and for $\alpha = 1$, also centred) sums of ε_t , belonging to the class of so-called stable distributions. Heavy tailed data are widely encountered in applied research; reported estimates of α include 1.85 for stock returns (McCulloch, 1997), above 1.5 for income, about 1.5 for wealth and trading volumes, about 1 for firm and city sizes (all in Gabaix, 2009, and references therein) and even below 1 for returns from technological innovations (Silverberg and Verspagen, 2007).

(ii) Part (b) of Assumption 1 imposes strict stationarity on X_t , guarantees almost sure convergence of $\sum_{i=0}^{\infty} \gamma_i \varepsilon_{t-i}$ (as well as some series in ε_t^2) and underlies the asymptotics for sample correlations (Davis and Resnick, 1985b, p.270, and 1986, p.547). This condition also implies that $\sum_{i=1}^{\infty} i^{2/\delta} |\gamma_i| < \infty$. Therefore, part (b) of Assumption 1 would also impose weak stationarity on X_t in the case where the mean and variance of ε_t were both finite and constant. Part (c) ensures that the MA polynomial, $\gamma(z)$, is invertible, while part (d) implies, among other things, that the infinite autoregressive series in (3) below converges absolutely with probability one. \square

Under Assumption 1 X_t in (2) is strictly stationary and invertible and, equivalently, solves the (potentially) infinite-order difference equation

$$X_t = \sum_{i=1}^{\infty} \beta_i X_{t-i} + \varepsilon_t, \quad t \in \mathbb{Z}. \quad (3)$$

The coefficients in (3) satisfy $\sum_{i=1}^{\infty} i^{2/\delta} |\beta_i| < \infty$ due to the analogous property imposed on the $\{\gamma_i\}$ in part (b) of Assumption 1; see Brillinger (2001, pp.76-77).

In this paper we study inference based on a sieve approximation to (3); this is obtained using the truncated autoregression

$$X_t = \sum_{i=1}^k \beta_i X_{t-i} + \varepsilon_{t,k} \quad (4)$$

where the lag truncation parameter, k , is an increasing function of the sample size. In (4), $\varepsilon_{t,k} := \varepsilon_t + \rho_{t,k}$ where $\rho_{t,k} := \sum_{i=k+1}^{\infty} \beta_i X_{t-i}$ represents the sieve approximation error. The OLS estimates of the sieve parameters $\beta_k := (\beta_1, \dots, \beta_k)'$ in (4), given the sample observations (X_1, \dots, X_T) , are given by $\hat{\beta}_k := (S_{00}^k)^{-1} \sum_{t=k+1}^T \mathbf{X}_{t-1}^k X_t =: (\hat{\beta}_1, \dots, \hat{\beta}_k)'$, where $S_{00}^k := \sum_{t=k+1}^T \mathbf{X}_{t-1}^k (\mathbf{X}_{t-1}^k)'$ with $\mathbf{X}_{t-1}^k = (X_{t-1}, \dots, X_{t-k})'$.

3 CONVERGENCE RESULTS FOR OLS SIEVE ESTIMATORS

Here we establish the large sample properties of the OLS estimators from the sieve regression (4) when the DGP is a linear process driven by IV innovations, as in (2). We initially show consistency of the OLS sieve estimators from (4). The usual Euclidean vector norm is denoted by $\|\cdot\|$.

THEOREM 1 *Let $\{X_t\}$ be generated according to (2) under the conditions of Assumption 1. Then, provided $1/k + k^2/T \rightarrow 0$ as $T \rightarrow \infty$, it follows that $\|\hat{\beta}_k - \beta_k\| = o_P(1)$.*

Having established the consistency properties of the OLS sieve estimators, we now turn to studying the asymptotic distributions (where they exist) of the OLS sieve estimators, demonstrating how the assumptions used so far need to be strengthened to achieve finer results. We begin by stating a lemma which shows how the asymptotic argument can be reduced to an analysis of the sample autocorrelations. This lemma employs some additional notation that we introduce and discuss next.

First, define $a_T := \inf\{x : P(|\varepsilon_1| > x) \leq T^{-1}\}$. By part (a) of Assumption 1, there exists a sequence l_T , slowly varying at infinity, such that $a_T = T^{1/\alpha} l_T$. For the case where $E|\varepsilon_1|^\alpha < \infty$ and $\lim_{t \rightarrow \infty} P(|\varepsilon_1 \varepsilon_2| > t) / P(|\varepsilon_1| > t) = 2E|\varepsilon_1|^\alpha$, define $\tilde{a}_T = a_T$; otherwise, define $\tilde{a}_T := \inf\{x : P(|\varepsilon_1 \varepsilon_2| > x) \leq T^{-1}\}$. In the latter case $\tilde{a}_T = a_T \tilde{l}_T$ for some \tilde{l}_T , slowly varying at infinity, such that $\tilde{l}_T \rightarrow \infty$ as $T \rightarrow \infty$; see Davis and Resnick (1985b, p.263, and 1986, p.542).

Second, define the infinite Toeplitz matrix $\Sigma := (r_{|i-j|})_{i,j=0}^{\infty}$ formed from the *scale-free autocovariances*, $r_{|i-j|} := \sum_{s=0}^{\infty} \gamma_s \gamma_{s+|i-j|}$. It is a standard fact that Σ generates a bounded operator on the space ℓ_2 of square summable sequences endowed with the Euclidean metric; see Theorem 1.9 of Böttcher and Silbermann (1999,p.10). Moreover, under Assumption 1, the operator generated by Σ is invertible; see Theorem 1.15 of Böttcher and Silbermann (1999, p.18). We denote the matrix of the inverse operator with respect to the canonical base of ℓ_2 by Σ^{-1} .

Finally, we denote by L a generic $m \times \infty$ selection matrix of constants, with (i, j) -th element l_{ij} , and let $L_k := (L_{\cdot 1}, \dots, L_{\cdot k})$ denote the matrix formed from the first k columns of L . The matrix L , and hence L_k , will determine the linear combination(s) of the coefficients, β_j , $j = 1, 2, \dots$ from (3) we are interested in conducting inference on, via constructing confidence intervals or, equivalently, testing hypotheses of the generic form $L\beta = l$, where $\beta := (\beta_1, \beta_2, \dots)'$ is the $\infty \times 1$ vector of AR coefficients from (3) and l is a $m \times 1$ vector of constants. For example: inference on β_1 would require $L = (1, 0, 0, \dots)$; inference involving the sum of β_1 and β_2 would require $L = (1, 1, 0, \dots)$; a joint simple hypothesis on β_1 and β_2 would require the first row of L to be as in the first example above and the second row to be $(0, 1, 0, \dots)$. We are now in a position to state our preparatory lemma.

LEMMA 1 *Let the conditions of Theorem 1 hold, and assume further that $a_T \sum_{i=k+1}^{\infty} |\beta_i| \rightarrow 0$ as $T \rightarrow \infty$. Also assume that there exists some $\delta' \in (\delta, \frac{2\alpha}{2+\alpha})$, where δ is as defined in part (a) of Assumption 1, such that the selection matrix L has δ' -summable rows under linear weighting (i.e. such that $\sum_{j=1}^{\infty} j |l_{ij}|^{\delta'} < \infty$, $i = 1, \dots, m$). Then, provided $1/k + k^3/T \rightarrow 0$ as $T \rightarrow \infty$, with the additional condition that k is not a slowly varying function of T for the particular value $\alpha = 1$, it holds that*

$$\|L_k\{(\hat{\beta}_k - \beta_k) - d_T\} - \sigma_T^{-2} \sum_{j=1}^{\infty} A_j \sum_{t=k+1}^T (\varepsilon_{t-j}\varepsilon_t - \mu_T)\| = o_P(a_T^{-2}\tilde{a}_T),$$

where: $d_T := (T-k)\gamma(1)\mu_T(S_{00}^k)^{-1}\mathbf{u}_k$ with $\mu_T := E(\varepsilon_1\varepsilon_2\mathbb{I}_{\{|\varepsilon_1\varepsilon_2| \leq \tilde{a}_T\}})$ and \mathbf{u}_k a k -dimensional vector of ones; $\sigma_T^2 := \sum_{t=k+1}^T \varepsilon_t^2$; finally, $A_j \in \mathbb{R}^m$ ($j \in \mathbb{N}$) are given by $A_j := \sum_{i=1}^j L(\Sigma^{-1})_{\cdot i} \gamma_{j-i}$.

REMARK 3.1. (i) The analogue of our condition $a_T \sum_{i=k+1}^{\infty} |\beta_i| \rightarrow 0$ in the finite-variance case is $T^{1/2} \sum_{i=k+1}^{\infty} |\beta_i| \rightarrow 0$; see Berk (1974) and Lewis and Reinsel (1985). Both conditions involve the order of magnitude of the (possibly centred) error sums $\sum_{t=1}^T \varepsilon_t$, respectively a_T and $T^{1/2}$ for infinite and finite variance. Our condition entails that k is, in general, required to grow at a faster rate the smaller is α . However, in the important special case of a finite-order autoregression, k is only required to be at least as large as the true autoregressive order, while in the case where the β_i , $i = 1, 2, \dots$ exhibit exponential decay (as happens for finite-order ARMA processes), any power rate of the form $k = T^r$ ($r \in (0, 1)$) is sufficient uniformly in α . As regards the summability condition on the rows of L , again a similar condition is imposed on L in the finite-variance case; see Theorem 2(iv) of Lewis and Reinsel (1985).

(ii) An important implication of the approximation given in Lemma 1 is that the large sample behavior of the OLS sieve estimator is determined by the same three cases for $\tilde{a}_T^{-1} \sum_{t=k+1}^T (\varepsilon_{t-j}\varepsilon_t - \mu_T)$ studied in Davis and Resnick (1985b,1986) as in the finite-order autoregressive setup discussed in the introduction. Cases (i) and (ii), where an asymptotic distribution exists, will be detailed in Theorem 2 below. Under case (iii), and as in Davis and Resnick (1985b), the OLS sieve estimators cannot be normalised such that a non-degenerate limiting distribution is obtained.

(iii) Given part (a) of Assumption 1 and the assumption of δ' -row-summability of L under linear weighting, the A_j ($j \in \mathbb{N}$) are also row-wise δ' -summable under linear weighting; that

is, $\sum_{j=1}^{\infty} j |A_{ij}|^{\delta'} < \infty$, $i = 1, \dots, m$ (see section 7.2). This property is sufficient for the series in Lemma 1 and Theorem 2 to be a.s. convergent, and, hence, for David and Resnick's (1985b and 1986) asymptotic theory for sample autocovariances to be applied in Theorem 2 below. Notice that the upper bound on δ' is used to control the convergence rate of the quantity $L_k \Sigma_k^{-1}$ to $L\Sigma$. \square

We now provide in Theorem 2 the asymptotic distribution of the OLS sieve estimator from (4) under Cases (i) and (ii) of the three possible cases outlined in section 1.

THEOREM 2 *Let the conditions of Lemma 1 hold, including the rate conditions on k imposed therein. Then:*

CASE (i): *If $\mathbb{E} |\varepsilon_t|^\alpha = \infty$, then*

$$a_T^2 \tilde{a}_T^{-1} L_k \{(\hat{\beta}_k - \beta_k) - d_T\} \xrightarrow{w} S^{-1} \sum_{j=1}^{\infty} A_j S_j, \quad (5)$$

where $\{S_j\}_{j=1}^{\infty}$ is an i.i.d. sequence of α -stable r.v.'s and S is an a.s. positive $\alpha/2$ -stable r.v. independent of $\{S_j\}_{j=1}^{\infty}$, with remaining notation as in Lemma 1; **CASE (ii):** *If $\mathbb{E} |\varepsilon_t|^\alpha < \infty$ and $\liminf_{t \rightarrow \infty} P(|\varepsilon_1 \varepsilon_2| > t) / P(|\varepsilon_1| > t) = 2 \mathbb{E} |\varepsilon_1|^\alpha$, then (5) holds with $a_T^2 \tilde{a}_T^{-1} = a_T$, and where $\{S_j\}_{j=1}^{\infty}$ and S are as described in Case (i) except that they are now dependent with joint distribution as given in Theorem 3.5 of Davis and Resnick (1985b).*

REMARK 3.2. (i) The requirement on the lag truncation parameter that $1/k + k^3/T \rightarrow 0$, as $T \rightarrow \infty$, is standard in analogous theorems in the finite-variance case; see, *inter alia*, Berk (1974, Theorem 6) and Lewis and Reinsel (1985, Theorem 2). However, this rate condition can be weakened in our setting to $1/k + k^{\max\{2, 1+\alpha\}+\zeta}/T \rightarrow 0$, as $T \rightarrow \infty$, for some $\zeta > 0$. Clearly this condition becomes weaker the further α is from 2, while approaching the usual k^3/T rate as α approaches 2. This weaker rate entails that k is allowed to grow at a faster rate the smaller is α .

(ii) If the distribution of $\{\varepsilon_1\}$ is symmetric (about zero), then so is the distribution of $\varepsilon_1 \varepsilon_2$, and the centering term d_T in (5) will be zero. If the distribution of $\{\varepsilon_1\}$ is asymmetric and $\alpha \in (0, 1) \cup (1, 2)$, then the centering of $(\hat{\beta}_k - \beta_k)$ can be omitted but at the cost of a location shift in S_j . In the case where $\alpha \in (0, 1)$ we have that $T \tilde{a}_T^{-1} \mu_T \rightarrow (2\tilde{p} - 1) \frac{\alpha}{1-\alpha}$ as $T \rightarrow \infty$, by Karamata's theorem (see Feller, 1971, p.283), where $\tilde{p} := p^2 + (1-p)^2$ (see Assumption 1(a)), and so omitting d_T requires S_j to be replaced by $\tilde{S}_j := S_j + (2\tilde{p} - 1) \frac{\alpha}{1-\alpha}$ in (5). For $\alpha \in (1, 2)$, omitting d_T requires S_j to be replaced by $S_j - \mathbb{E} S_j = S_j + (2\tilde{p} - 1) \frac{\alpha}{1-\alpha}$ again. The centering cannot in general (other than in the symmetric case) be omitted when $\alpha = 1$.

(iii) If the distribution of $\{\varepsilon_1\}$ is symmetric (about zero), then so is the distribution of S_j . In this case the i -th component of the limit distribution in (5) is equal in distribution to $(\sum_{j=1}^{\infty} |A_{ji}|^\alpha)^{1/\alpha} S_1/S$. This is analogous to the the finite-variance case, where the same holds with $\alpha = 2$, S_1 standard Gaussian and $S = 1$. If a consistent estimator $\hat{\alpha}$ of α were available, then $(\sum_{j=1}^{\infty} |A_{ji}|^\alpha)^{1/\alpha}$ could be consistently estimated. If a studentising statistic growing at the rate of $a_T^{-2} \tilde{a}_T$ were available (which is in itself an open question, as pointed out by a referee), then an asymptotic test for one-dimensional restrictions could be constructed by reference to the quantity S_1/S . However, and in contrast to the the finite-variance case, it does not seem possible to find a full-rank linear transformation of the limit in (5) which depends on α alone, precluding a similar simplification of the joint asymptotic test of several restrictions. \square

The asymptotic results given in this section highlight the infeasibility of classical asymptotic inference for testing linear hypotheses (or constructing confidence intervals) concerning the elements of β . In particular, as Remark 3.2(ii) makes clear, even under the special case

discussed there inference would still not be feasible without knowledge of which of Cases (i) and (ii) held (and indeed, that it was one of these cases, rather than Case (iii) which held). An obvious alternative therefore, which we consider in the next section, is to explore bootstrap methods of inference, which may be thought of as a device for approximating the finite sample distributions of the test statistics involved. As in practice it is rarely clear if the data exhibit IV, it will be desirable to have available bootstrap procedures that are valid for testing hypotheses concerning the parameters of linear processes driven either by finite variance or IV innovations.

4 BOOTSTRAP METHODS

In this section we propose and discuss three bootstrap methods of inference for IV linear processes. First, we consider the wild bootstrap (based on random sign changes in the residuals), which for the benchmark problem of inference on the location has been shown to be robust to errors with symmetric IV distributions; see Cavaliere *et al.* (2013). LePage (1992) also shows that a wild bootstrap based on random signs can yield very significant improvements in precision since it approximates a conditional version of the test statistic's distribution. Importantly for precision, in the IV case the randomness due to conditioning remains in the limiting distribution of the bootstrap statistic, in contrast to what happens in the finite-variance case. An alternative to the wild bootstrap, which approximates a different conditional distribution of the test statistic with asymptotic randomness, is the permutation bootstrap proposed by LePage and Podgorski (1996) in the context of regressions with fixed regressors and IV errors. Unlike the wild bootstrap, the permutation bootstrap does not require the assumption of distributional symmetry. Finally, we also consider a hybrid of these two, which we term the permuted wild bootstrap, where the residuals are permuted and their signs drawn randomly.

In the problem of inference on the location (Cavaliere *et al.* 2013), a particularity of the wild bootstrap statistic used is permutation-invariance. Only two of the three bootstrap schemes outlined above will deliver statistics which have permutation-invariant distributions in the present setting and it will turn out to matter for the asymptotic properties of the bootstrap approximation. Specifically, unlike the location case, here bootstrap statistics computed by randomly changing the signs of the residuals (as is done with the wild bootstrap) are not permutation invariant; they are used to approximate the distribution of the test statistics conditional on (essentially) $\{|\varepsilon_t|\}_{t=k+1}^T$ and this distribution changes when the elements in this sequence are reshuffled. To obtain a permutation-invariant reference distribution, the residuals need to be permuted explicitly, resulting in an approximation to the distribution of test statistics conditional on (essentially) the order statistics of $\{\varepsilon_t\}_{t=k+1}^T$ and $\{|\varepsilon_t|\}_{t=k+1}^T$ for the permutation bootstrap and the permuted wild bootstrap, respectively. Moreover, because random permuting effectively enlarges the reference population, the reference distributions for the permutation bootstrap and the permuted wild bootstrap can be expected to be more dispersed than that of the pure wild bootstrap, illustrating a cost of achieving permutation invariance.

4.1 BOOTSTRAP IMPLEMENTATIONS

In Algorithm 1 below we formalise the three bootstrap schemes that we will analyse in this section. To simplify notation and ease exposition, we shall assume that L and L_k are $1 \times \infty$ and $1 \times k$, respectively, corresponding to the case of a single linear restriction of the form $L\beta = l$. Moreover, we shall not studentise the test statistics. Corresponding results for Wald-type tests of multiple restrictions will be discussed in Remark 4.2(ix).

ALGORITHM 1.

Step (i) Estimate (4) by OLS to yield the sieve estimates, $\hat{\beta}_i$, $i = 1, \dots, k$, and the corresponding residuals, $\hat{\varepsilon}_t := X_t - \hat{\beta}'_k \mathbf{X}_{t-1}^k$, $t = k+1, \dots, T$.

Step (ii) Generate the bootstrap errors $\varepsilon_t^* := \hat{\varepsilon}_{\pi(t)} w_t$, $t = k+1, \dots, T$, where two options are considered for each of π and $\{w_t\}_{t=k+1}^T$, namely: $(\boldsymbol{\pi}_{id})$ $\pi(t) = t$, i.e., π is the identity function on $\{k+1, \dots, T\}$, or $(\boldsymbol{\pi}_R)$ π is a random permutation of $\{k+1, \dots, T\}$, and (\mathbf{w}_1) $w_t = 1$ ($t = k+1, \dots, T$), or (\mathbf{w}_R) w_t are i.i.d. Rademacher r.v.'s ($w_t = \pm 1$ each occurring with probability $\frac{1}{2}$). In all options, π and $\{w_t\}_{t=k+1}^T$ are independent of each other and the data. The combinations $(\boldsymbol{\pi}_{id}, \mathbf{w}_R)$, $(\boldsymbol{\pi}_R, \mathbf{w}_1)$ and $(\boldsymbol{\pi}_R, \mathbf{w}_R)$ correspond respectively to the wild bootstrap, permutations bootstrap and permuted wild bootstrap.

Step (iii) Construct the bootstrap sample using the recursion

$$X_t^* := \begin{cases} X_t & t = 1, \dots, k \\ \sum_{i=1}^k \hat{\beta}_i X_{t-i}^* + \varepsilon_t^* & t = k+1, \dots, T \end{cases} \quad (6)$$

and define the bootstrap product moment matrices $S_{00}^{*k} := \sum_{t=k+1}^T \mathbf{X}_{t-1}^{*k} (\mathbf{X}_{t-1}^{*k})'$ and $S_{0\varepsilon}^{*k} := \sum_{t=k+1}^T \mathbf{X}_{t-1}^{*k} \varepsilon_t^*$ with $\mathbf{X}_{t-1}^{*k} := (X_{t-1}^*, \dots, X_{t-k}^*)'$. The bootstrap analogue of the OLS sieve estimator, $\hat{\beta}_k^*$, is $\hat{\beta}_k^* := (S_{00}^{*k})^{-1} \sum_{t=k+1}^T \mathbf{X}_{t-1}^{*k} X_t^*$.

Step (iv) Define the bootstrap statistic $L_k(\hat{\beta}_k^* - \hat{\beta}_k) = L_k(S_{00}^{*k})^{-1} S_{0\varepsilon}^{*k}$ and use its distribution conditional on the data to approximate an appropriate conditional distribution of $L_k(\hat{\beta}_k - \beta_k)$.

REMARK 4.1. (i) As is standard, the distribution of the bootstrap statistic $L_k(\hat{\beta}_k^* - \hat{\beta}_k)$ conditional on the data is approximated by numerical simulation. This is achieved by generating B (conditionally) independent bootstrap statistics, $L_k(\hat{\beta}_k^{*(b)} - \hat{\beta}_k)$, $b = 1, \dots, B$, computed as in Algorithm 1 above, with B large. The respective B simulated quantiles are then used as approximations for the quantiles of $L_k(\hat{\beta}_k - \beta_k)$. For instance, in the case where inference is on the null hypothesis $H_0 : L\beta = l$ against the (one sided) alternative $H_1 : L\beta > l$, the bootstrap p-value associated to the original test statistic $L_k \hat{\beta}_k - l$ is computed as $\tilde{p}_T^* := B^{-1} \sum_{b=1}^B \mathbb{I}(L_k(\hat{\beta}_k^{*(b)} - \hat{\beta}_k) > L_k \hat{\beta}_k - l)$.

(ii) Notice that in the implementation of the bootstrap procedures proposed in Algorithm 1, deterministic normalising sequences (such as $T^{1/2}$ or $a_T^2 \tilde{a}_T^{-1}$ as in Theorem 2), are not required when applied simultaneously to the original and bootstrap statistics, as bootstrap test outcomes are invariant to scaling. This exempts one from the need to decide on an appropriate normalising sequence in applications and, in particular, is important for the robustness of bootstrap tests based on the finite-variance normalisation $T^{1/2}$ to the presence of IV. Nevertheless, normalisation is necessary in the asymptotic analysis of the bootstrap to prevent the statistics at hand from vanishing as T diverges. \square

4.2 ASYMPTOTIC THEORY FOR THE BOOTSTRAP

The next theorem, in the style of LePage and Podgorski (1996), characterizes the large sample properties of the three bootstrap methods introduced in Algorithm 1. It concerns the proximity (in the Lévy metric ρ_L) of finite-sample distribution functions as $T \rightarrow \infty$. Specifically, for a given $\eta > 0$, η -proximity of two cdfs F and F^* at a point x is evaluated by means of the indicator

$$I_\eta^{F, F^*}(x) := \mathbb{I}(F^*(x - \eta) - \eta \leq F(x) \leq F^*(x + \eta) + \eta).$$

Then, for F a (conditional) distribution function of $a_T^2 \tilde{a}_T^{-1} L_k(\hat{\beta}_k^* - \beta_k)$, and F^* a (conditional) distribution function of the bootstrap statistic $a_T^2 \tilde{a}_T^{-1} L_k(\hat{\beta}_k^* - \hat{\beta}_k)$, we will provide

sufficient conditions such that the Lévy distance between F and F^* vanishes in probability as T diverges:

$$\rho_L(F, F^*) \xrightarrow{P} 0, \rho_L(F, F^*) := \inf\{\eta > 0 : \forall x \in \mathbb{R}, I_\eta^{F, F^*}(x) = 1\}.$$

In the theorem, we will discuss two forms of the bootstrap statistic. Along with $L_k(\hat{\beta}_k^* - \hat{\beta}_k)$, which is the usual bootstrap analogue of $L_k(\hat{\beta}_k - \beta_k)$, we will consider an infeasible bootstrap statistic of the form $L_k(\hat{\beta}_k^* - \hat{\beta}_k + \Delta\hat{\beta}_k^*)$, where $\Delta\hat{\beta}_k^* := (S_{00}^{*k})^{-1}\{\sum_{t=k+1}^T w_t \mathbf{X}_{t-1}^{*k} (\mathbf{X}_{t-1}^k)'\}(\hat{\beta}_k - \beta_k)$ is a correction term. Although this statistic cannot be computed in practice, it allows us to shed some light on the properties of the wild bootstrap approximation in the present framework. The statistics are normalised as in Lemma 1 and Theorem 2; see also Remark 4.2.(viii) below.

THEOREM 3 *Let $\{X_t\}$ be generated according to (2) under Assumption 1. Let L be such that $\sum_{i=1}^\infty |L \cdot i|^\delta < \infty$, where δ is as given in Assumption 1. Moreover, let F^* and $F^{*,\Delta}$ denote the bootstrap distribution functions conditional on the data of, respectively, $a_T^2 \tilde{a}_T^{-1} L_k(\hat{\beta}_k^* - \hat{\beta}_k)$ and $a_T^2 \tilde{a}_T^{-1} L_k(\hat{\beta}_k^* - \hat{\beta}_k + \Delta\hat{\beta}_k^*)$. For distribution functions viewed as stochastic processes on the probability space where $\{\varepsilon_t\}_{t=-\infty}^\infty$ are defined, and provided k is such that $1/k + k^5/T \rightarrow 0$ and $a_T \sum_{i=k+1}^\infty |\beta_i| \rightarrow 0$ as $T \rightarrow \infty$, it holds that:*

(a) *If $\{\varepsilon_t\}$ is symmetrically distributed, then $\rho_L(F^{*,\Delta}, F^{|\varepsilon|}) \rightarrow 0$ for the wild bootstrap, (π_{id}, \mathbf{w}_R) , where $F^{|\varepsilon|}$ denotes the distribution function of $a_T^2 \tilde{a}_T^{-1} L_k(\hat{\beta}_k - \beta_k)$ conditional on $\{|\varepsilon_t|\}_{t=-\infty}^T$.*

(b) *Provided $k^{1+2/\alpha+\zeta}/T \rightarrow 0$ for some $\zeta > 0$ if $\alpha \leq \frac{1}{2}$, then $\rho_L(F^*, F^e) \rightarrow 0$ for the permutations bootstrap, (π_R, \mathbf{w}_1) , where F^e denotes the distribution function of $a_T^2 \tilde{a}_T^{-1} L_k(\hat{\beta}_k - \beta_k)$ conditional on $\{\varepsilon_t\}_{t=-\infty}^k$ and the order statistics of $\{\varepsilon_t\}_{t=k+1}^T$.*

(c) *If $\{\varepsilon_t\}$ is symmetrically distributed, and provided $k^{1+2/\alpha+\zeta}/T \rightarrow 0$ for some $\zeta > 0$ if $\alpha \leq \frac{1}{2}$, then $\rho_L(F^*, F^{|\varepsilon|}) \rightarrow 0$ for the permuted wild bootstrap, (π_R, \mathbf{w}_R) , where $F^{|\varepsilon|}$ denotes the distribution function of $a_T^2 \tilde{a}_T^{-1} L_k(\hat{\beta}_k - \beta_k)$ conditional on $\{|\varepsilon_t|\}_{t=-\infty}^k$ and the order statistics of $\{|\varepsilon_t|\}_{t=k+1}^T$.*

REMARK 4.2. (i) The result in part (a) of Theorem 3 shows that an asymptotically exact (in the Lévy metric) approximation of $F^{|\varepsilon|}$ by the wild bootstrap requires the addition of the correction term, $\Delta\hat{\beta}_k^*$, to $\hat{\beta}_k^* - \hat{\beta}_k$. In contrast, parts (b) and (c) establish that the permutation bootstrap and the permuted wild bootstrap approximations of, respectively, F^e and $F^{|\varepsilon|}$ are consistent (in the Lévy metric) with no need for a correction. Some further clarifications in regard to this are given in Remarks 4.2(iv)-4.2(vii) below.

(ii) Because $L\beta = L_k\beta_k + o(a_T^{-2}\tilde{a}_T)$ under the conditions of Theorem 3, the results there hold with $L_k(\hat{\beta}_k - \beta_k)$ replaced by $L_k\hat{\beta}_k - L\beta$. Hence, the corrected wild, permutation and permuted wild bootstraps always approximate a (conditional) distribution of $\tau := a_T^2 \tilde{a}_T^{-1} (L_k\hat{\beta}_k - L\beta)$ for the true $L\beta$. Under the null hypothesis $H_0 : L\beta = l$, the bootstraps approximate a distribution of the test statistic $\tau^0 := a_T^2 \tilde{a}_T^{-1} (L_k\hat{\beta}_k - l)$ since $\tau^0 = \tau$. On the other hand, if H_0 does not hold, then $\tau^0 = \tau + a_T^2 \tilde{a}_T^{-1} (L\beta - l)$ diverges at rate $a_T^2 \tilde{a}_T^{-1}$, while it can be seen that (under the conditional probability measures of Theorem 3) τ , and, hence, its consistent distributional approximations by the bootstrap, have lower orders of magnitude. This implies consistency of the bootstrap tests of H_0 . The test based on the uncorrected wild bootstrap is consistent for similar reasons.

(iii) Although in the case where $\alpha \leq \frac{1}{2}$ additional rate conditions have been placed on k in parts (b)-(c) of Theorem 3 in order to obtain the stated results in a reasonably tractable

way, we conjecture that these extra conditions could be weakened. However, given the very limited empirical relevance of distributions with small α , we have not attempted to do so.

(iv) The use of the correction term $\Delta\hat{\beta}_k^*$ is asymptotically equivalent to using the true $\varepsilon_{t,k}w_t$ instead of $\varepsilon_t^* = \hat{\varepsilon}_t w_t$ in the generation of the bootstrap data X_t^* . The correction term can only be calculated if β is completely specified under the null hypothesis (specifying $L\beta$ alone is not enough as $(S_{00}^{*k})^{-1}\{\sum_{t=k+1}^T w_t \mathbf{X}_{t-1}^{*k} (\mathbf{X}_{t-1}^k)'\}$ is not asymptotically equivalent to a scalar matrix). Therefore, it is of limited practical interest. Nevertheless, it can be calculated in a simulation experiment in order to evaluate its effect on the finite-sample performance of the bootstrap, as we shall do in Section 5 below.

(v) Under IV, without permuting the residuals, the term $\Delta\hat{\beta}_k^*$ is not asymptotically negligible compared to $\hat{\beta}_k - \beta_k$. In fact, conditionally on the data, the terms S_{00}^{*k} and $\sum_{t=k+1}^T w_t \mathbf{X}_{t-1}^{*k} (\mathbf{X}_{t-1}^k)'$ have the same order of magnitude in probability as the squared extremes of the data, and so $\Delta\hat{\beta}_k^*$ has the same order of magnitude as $\hat{\beta}_k - \beta_k$.

(vi) The term $\Delta\hat{\beta}_k^*$ is not related to the fact that we do not centre the residuals, nor to the approximate nature of the autoregressions we estimate. The same correction would be necessary even for an i.i.d. process with IV errors ($\gamma_i = 0$, $i \in \mathbb{N}$) to which an exact finite-order autoregression is fitted (say, with $k = 1$ and coefficient β). Without permuting, in that ($k = 1$) case

$$\Delta\beta^* = \hat{\beta} \left(\sum_{t=3}^T \varepsilon_{t-1}^2 \right)^{-1} \left(\sum_{t=3}^T \varepsilon_{t-1}^2 w_{t-1} w_t \right) + o_{P^*}(\hat{\beta}) \quad (7)$$

in P -probability, where P^* denotes probability conditional on the data. Then, in the sense of weak convergence of random measures,

$$\mathcal{L} \left(\frac{\sum_{t=3}^T \varepsilon_{t-1}^2 w_{t-1} w_t}{\sum_{t=3}^T \varepsilon_{t-1}^2} \middle| \{\varepsilon_t\}_{t=2}^{T-1} \right) \xrightarrow{w} \mathcal{L} \left(\frac{\sum_{i=1}^{\infty} \tau_i^{-2/\alpha} \delta_i}{\sum_{i=1}^{\infty} \tau_i^{-2/\alpha}} \middle| \{\tau_i\}_{i=1}^{\infty} \right)$$

with τ_i ($i \in \mathbb{N}$) distributed as the arrival times of a Poisson process with intensity one, and $\{\delta_i\}$ an i.i.d. sequence of Rademacher r.v.'s jointly independent of $\{\tau_i\}_{i \in \mathbb{N}}$ (LePage, Woodroffe and Zinn, 1981). Rather, the correction is made necessary by the IV of the regressors. This is in contrast to the case where $\sum_{t=3}^T \varepsilon_{t-1}^4 (\sum_{t=3}^T \varepsilon_{t-1}^2)^{-2} = o_P(1)$, e.g., when $E \varepsilon_1^4 < \infty$.

(vii) In the context of Remark 4.2(vi), if a random permutation, say π , is applied to the residuals, then the following expansion holds in place of (7):

$$\Delta\beta^* = \hat{\beta} \left(\sum_{t=3}^T \varepsilon_{t-1}^2 \right)^{-1} \left(\sum_{t=3}^T \varepsilon_{\pi(t-1)} \varepsilon_{\pi(t)-1} w_{t-1} w_t \right) + o_{P^*}(\hat{\beta}) \quad (8)$$

in P -probability. Because $\pi(t-1) \neq \pi(t) - 1$ with high probability, the random permutation avoids, with high probability, the squaring of errors in the numerator of $\Delta\beta^*$, in contradistinction to (7). Intuitively, since the cumulation of mixed products of errors is of lower stochastic magnitude order than the cumulation of squared errors, the order of magnitude of the leading term in expansion (8) is lower than in (7). A rough but sufficient formal estimate confirming this is

$$E^* \left| \frac{\sum_{t=3}^T \varepsilon_{\pi(t-1)} \varepsilon_{\pi(t)-1} w_{t-1} w_t}{\sum_{t=3}^T \varepsilon_{t-1}^2} \right| \leq \frac{1}{T-3} \frac{(\sum_{t=1}^T |\varepsilon_t|)^2}{\sum_{t=3}^T \varepsilon_{t-1}^2} = o_P(1),$$

where $\sum_{t=3}^T \varepsilon_{t-1}^2 = O_P(a_T^2)$, and $\sum_{t=1}^T |\varepsilon_t|$ is $O_P(a_T)$, $O_P(Tl_T)$ and $O_P(T)$ respectively for $\alpha \in (0, 1)$, $\alpha = 1$ and $\alpha \in (1, 2)$, with l_T slowly varying at infinity. Hence, by Markov's inequality, $\Delta\beta^* = o_{P^*}(\hat{\beta})$ in P -probability and no correction of the bootstrap statistic is necessary.

(viii) Theorem 3 employs normalisation by the rates from the unconditional analysis of mean corrected estimators (see Lemma 1 and Theorem 2), but does not employ the mean correction itself. Omitting the mean correction may affect the order of magnitude of the estimators (by a multiplicative slowly varying factor) only for the case of asymmetric errors with $\alpha = 1$ (see Remark 3.2(iii)). The bootstrap approximations remain valid also if the statistics are divided by this extra factor because the conclusions of Theorem 3 can be shown to hold also if the normalisation sequence $a_T^2 \tilde{a}_T^{-1}$ is replaced by $a_T^{1+\epsilon}$ for small $\epsilon > 0$ (for the wild bootstrap, under the extra condition that $a_T^{1+\epsilon} \sum_{i=k+1}^{\infty} |\beta_i| \rightarrow 0$ as $k \rightarrow \infty$).

(ix) To test m linear restrictions on β , written as $L\beta = l$, where L satisfies the assumptions of Lemma 1, a Wald statistic can be used:

$$W := T\hat{\sigma}_T^{-2}(L_k\hat{\beta}_k - l)'[L_k(S_{00}^k)^{-1}L_k']^{-1}(L_k\hat{\beta}_k - l),$$

where $\hat{\sigma}_T^2 := \sum_{t=k+1}^T \hat{\varepsilon}_t^2$. Critical values from conditional distributions of W (with the three conditioning options as in parts (a)-(c) of Theorem 3) can be approximated using the bootstrap distribution of the bootstrap counterparts (respectively feasible and infeasible),

$$\begin{aligned} W^* &:= T(\sigma_T^{*2})^{-1}(\hat{\beta}_k^* - \hat{\beta}_k)'L_k'[L_k(S_{00}^{*k})^{-1}L_k']^{-1}L_k(\hat{\beta}_k^* - \hat{\beta}_k) \\ W_{\Delta}^* &:= T(\sigma_T^{*2})^{-1}(\hat{\beta}_k^* - \hat{\beta}_k + \Delta\hat{\beta}_k^*)'L_k'[L_k(S_{00}^{*k})^{-1}L_k']^{-1}L_k(\hat{\beta}_k^* - \hat{\beta}_k + \Delta\hat{\beta}_k^*) \end{aligned}$$

where σ_T^{*2} is the sum of squared residuals for the bootstrap data. The properties of the bootstrap approximation are analogous to those stated in Theorem 3 for the univariate non-studentised statistics. More specifically, in the appendix we show that if $a_T^2 \tilde{a}_T^{-1} L_k(\hat{\beta}_k - \beta_k)$, $a_T^2 \tilde{a}_T^{-1} L_k(\hat{\beta}_k^* - \hat{\beta}_k)$ and $a_T^2 \tilde{a}_T^{-1} L_k(\hat{\beta}_k^* - \hat{\beta}_k + \Delta\hat{\beta}_k^*)$ are replaced by $a_T^4 \tilde{a}_T^{-2} T^{-1}W$, $a_T^4 \tilde{a}_T^{-2} T^{-1}W^*$ and $a_T^4 \tilde{a}_T^{-2} T^{-1}W_{\Delta}^*$ respectively, the conclusions of Theorem 3 remain valid, provided the row sequences of L decay sufficiently fast (cf. Lemma 1).

5 FINITE SAMPLE PROPERTIES

We now present results from a small Monte Carlo simulation study comparing the finite sample size and power properties of the three bootstrap procedures from Algorithm 1, together with a standard i.i.d. bootstrap, an ‘ m out of n ’ bootstrap and a non-bootstrap test which uses a critical value from the standard Gaussian distribution. Throughout the section, the wild bootstrap is based on centred residuals, as we found that centring tends to attenuate the size distortions due to the inconsistency (see Remark 4.2(i)) of this bootstrap method. As a benchmark for comparison, results for the infeasible corrected version of the wild bootstrap discussed in Remark 4.2(iv) are also included in the cases of symmetric errors (where the correction is asymptotically valid). The reference DGP is the MA(1)

$$X_t = \varepsilon_t + \gamma\varepsilon_{t-1}, \quad t = 1, \dots, T \quad (9)$$

with $\gamma \in \{\pm 0.4, 0\}$ and $T \in \{100, 500\}$. The errors $\{\varepsilon_t\}_{t=0}^T$ are i.i.d. draws from one of the following *stable* distributions: (1) symmetric with $\alpha = 1$ (Cauchy); (2) asymmetric with $\alpha = 1$ and asymmetry parameter 0.75; (3) symmetric with $\alpha = 1.5$; (4) asymmetric with $\alpha = 1.5$ and asymmetry parameter 0.75. As a benchmark case we also include: (5) the standard Gaussian distribution ($\alpha = 2$).

We evaluate the finite-sample size and power properties of tests for the null hypothesis $H_0 : \beta_1 = \bar{\beta}$ against the two-sided alternative $H_1 : \beta_1 \neq \bar{\beta}$ in the context of the sieve autoregression (4) with k chosen such that the condition in Theorem 3 that $1/k + k^5/T \rightarrow 0$ as $T \rightarrow \infty$ is satisfied. The same value of k is used in step (iii) of Algorithm 1. Results are reported for the (two-sided) studentised t -type version of the bootstrap tests (see Remark 4.2(ix)) at

Notes: (i) Tests of $H_0 : \beta_1 = \bar{\beta}$ with $\bar{\beta} = \gamma$ under the null hypothesis. (ii) ‘Wild’, ‘Perm.-Wild’, ‘Permutation’, ‘iid’, and ‘m/n’, denote the wild, permuted wild hybrid, permutation, i.i.d. and ‘ m out of n ’ bootstraps, respectively, based on studentised tests; (iii) ‘ t_N ’ denotes the (non-bootstrapped) studentised test based on standard Gaussian critical values; (iv) ‘Wild (corr.)’ indicates the infeasible wild bootstrap with the correction term included, see Remark 4.2(iv); (v) the lag truncation in both the sieve regression (4) and its bootstrap analogue is set to $k = \lfloor 25T^{1/5} / \ln T \rfloor$; the size of the ‘ m out of n ’ bootstrap samples is set to $m = \lfloor 3T / \ln T \rfloor$.

the nominal 5% level (tests based on non-studentised statistics behave very similarly and so are not reported). The results are based on 10000 Monte Carlo and $B = 1499$ bootstrap repetitions.

Empirical rejection frequencies (ERFs) under the true null hypothesis, $H_0 : \beta_1 = \gamma$, are reported in Table 1. The results for stable symmetric cases (1) and (3) suggest that the permutation and hybrid bootstraps outperform the wild bootstrap, ‘ m out of n ’ bootstrap and i.i.d. bootstrap procedures as well as the t_N test in terms of finite-sample size control. The same observation can be made for the asymmetric stable cases (2) and (4), although here we do observe a degree of oversizing for the hybrid bootstrap in case (2) when $T = 500$ (recall that the hybrid bootstrap was not shown to be theoretically valid under asymmetry). As expected on theoretical grounds, the wild bootstrap test under cases (1)-(4) is oversized, with size distortions appearing to increase slightly, other things being equal, as the sample size is increased. Notice also that the infeasible corrected wild bootstrap appears to, if anything, overcorrect in small samples. Under case (5), where the errors are Gaussian, all of the procedures are asymptotically valid and little is seen between them, save to note that the ‘ m out of n ’ bootstrap remains moderately undersized.

ERFs under the false null hypotheses $H_0 : \beta_1 = \bar{\beta}$ for $\bar{\beta} \in \{-0.1, 0.1\}$ when in fact $\gamma = 0$ are provided in Table 2. The reported results show that under cases (1)-(4) the permutation and hybrid bootstraps, and to an even greater extent, the wild bootstrap, can lead to significantly more powerful tests than their i.i.d. and ‘ m out of n ’ bootstrap counterparts, as well as the t_N test. Power gains are particularly apparent for $T = 100$ and are considerably greater for $\alpha = 1$ *vis-à-vis* $\alpha = 1.5$, other things equal. These results are consistent with previous evidence in the literature (LePage, 1992; see also the first two paragraphs of section 4) documenting that in the IV case, inference based on conditional distributions tends to be more precise relative to unconditional inference. The precision gains decrease when α approaches 2, as the conditional distributions get closer to the corresponding unconditional

TABLE 2

distributions (at least in large samples).

It should be recalled, however, that the wild bootstrap is not size controlled, and this is the price one pays for the additional finite sample power it displays relative to the permuted and hybrid bootstraps under cases (1)-(4). Taking these two aspects of the wild bootstrap together, these results are arguably in accordance with a strand in the recent literature on the possible finite-sample advantages of inconsistent bootstrap procedures with respect to their consistent modifications (Samworth, 2003; cf. Pötscher and Leeb, 2009, for inconsistent model selection). The permutation and hybrid bootstraps display almost identical power throughout, suggesting that the permutation bootstrap should be preferred, given its theoretical validity under both symmetric and asymmetric stable cases.

Overall, our Monte Carlo results suggest that, in particular in situations where the practitioner desires inference robust to the possibility of IV, rather than inference specifically designed for the case of IV, the implementation of OLS estimation in conjunction with the permutation and hybrid bootstrap methods appears to be very useful. Furthermore, the wild bootstrap may also constitute a relevant inference device, given its validity in finite variance autoregressive models (Kreiss, 1997; Gonçalves and Kilian, 2007) and its superior power properties under IV.

6 FURTHER APPLICATIONS

In this section we briefly discuss how our results can be applied to the examples of analysing the impulse response (MA) coefficients and the power transfer function (scale-free spectral density) of the process. Proofs of the results in Corollaries 1 and 2 can be found in the appendix.

Theorem 1 can be used to obtain the consistency properties of the associated sieve-based estimates of the impulse response (MA) coefficients in (2). To that end, let $\gamma_k := (\gamma_1, \dots, \gamma_k)'$ denote the vector formed from the first k MA coefficients from (2). It is well known that γ_k and β_k are related via the recursive relation $\gamma_k \equiv \Gamma_k \beta_k$, where Γ_k is the lower triangular

Toeplitz matrix with first column $(1 : \gamma'_{k-1})'$. Given $\hat{\beta}_k$, a sieve-based estimator of γ_k can therefore be obtained via the recursive relations $\hat{\gamma}_k \equiv \hat{\Gamma}_k \hat{\beta}_k$, where $\hat{\Gamma}_k$ is the lower triangular Toeplitz matrix with first column $(1 : \hat{\gamma}'_{k-1})'$. The consistency of $\hat{\gamma}_k =: (\hat{\gamma}_1, \dots, \hat{\gamma}_k)'$ for γ_k is established in the following corollary of Theorem 1.

COROLLARY 1 *Let the conditions of Theorem 1 hold. Then, provided $1/k + k^2/T \rightarrow 0$ as $T \rightarrow \infty$, it follows that $\|\hat{\gamma}_k - \gamma_k\| = o_P(1)$.*

The impulse response estimates, $\hat{\gamma}_1, \dots, \hat{\gamma}_k$, can in turn be used to obtain a sieve-based estimate of the power transfer function (scale-free spectral density) of the process X_t , $C(\lambda) := |1 + \sum_{j=1}^{\infty} \gamma_j e^{ij\lambda}|^2$, $\lambda \in (-\pi, \pi]$, where \mathbf{i} is the imaginary unit. Specifically, the sieve-based estimator of $C(\lambda)$ is given by $\hat{C}_T(\lambda) := |1 + \sum_{j=1}^k \hat{\gamma}_j e^{ij\lambda}|^2$, $\lambda \in (-\pi, \pi]$. The following corollary of Theorem 1 establishes the uniform consistency of this estimator.

COROLLARY 2 *Let the conditions of Theorem 1 hold. Then, provided $1/k + k^2/T \rightarrow 0$ as $T \rightarrow \infty$, it follows that $\sup_{\lambda \in (-\pi, \pi]} |\hat{C}_T(\lambda) - C(\lambda)| = o_P(1)$.*

We now use Theorem 2 to obtain the asymptotic distribution of the sieve-based estimate $\hat{\gamma}_k$, introduced above, of the vector of the first k impulse response coefficients in (2), γ_k , via the relation $\hat{\gamma}_k - \gamma_k \equiv \hat{\Gamma}_k \hat{\beta}_k - \Gamma_k \beta_k$.

COROLLARY 3 *Let the conditions of Theorem 2 hold, including the rate conditions on k stated therein. Then, $a_T^2 \tilde{a}_T^{-1} L_k \{(\hat{\gamma}_k - \gamma_k) - \hat{\Gamma}_k^2 d_T\} \xrightarrow{w} S^{-1} \sum_{j=1}^{\infty} \tilde{A}_j S_j$, where S and $\{S_j\}_{j=1}^{\infty}$ are as under Cases (i) and (ii) in Theorem 2, and where $\tilde{A}_j := \sum_{i=1}^j L \Gamma^2 (\Sigma^{-1})_{\cdot i} \gamma_{j-i}$ ($j \in \mathbb{N}$) and Γ is the infinite-order lower triangular Toeplitz matrix with first column $\gamma := (1, \gamma_1, \gamma_2, \dots)'$. The centering term, $\hat{\Gamma}_k^2 d_T$, can again be omitted under the circumstances outlined in Remark 3.2(ii).*

The bootstrap schemes outlined in Section 4 extend naturally to tests of restrictions on the MA coefficients $\gamma^1 := (\gamma_1, \gamma_2, \dots)'$. For example, for a null hypothesis of the form $L\gamma^1 = l$, where L satisfies the assumptions of Lemma 1, in the Wald statistics W and W^* one should replace $L_k \hat{\beta}_k - l$, $L_k (S_{00}^k)^{-1} L'_k$, $\hat{\beta}_k^* - \hat{\beta}_k$ and $L_k (S_{00}^{*k})^{-1} L'_k$ by $L_k \hat{\gamma}_k - l$, $L_k \hat{\Gamma}_k^2 (S_{00}^k)^{-1} \hat{\Gamma}_k'^2 L'_k$, $\hat{\gamma}_k^* - \hat{\gamma}_k$ and $L_k (\hat{\Gamma}_k^*)^2 (S_{00}^{*k})^{-1} (\hat{\Gamma}_k^{*'})^2 L'_k$ respectively, where $\hat{\gamma}_k^*$ is obtained from $\hat{\beta}_k^*$ through the recursive relations $\hat{\gamma}_k^* := \hat{\Gamma}_k^* \hat{\beta}_k^*$, with $\hat{\Gamma}_k^*$ denoting a Toeplitz lower triangular matrix with first column $(1 : \hat{\gamma}_{k-1}^{*'})'$.

7 PROOFS

We employ the matrix norms $\|\cdot\|_2 := \sup_{\|x\|=1} \|(\cdot)x\|$ induced by the Euclidean vector norm and $\|\cdot\| := [\text{tr}\{(\cdot)'(\cdot)\}]^{1/2}$, with tr denoting the trace operator. In particular, for square positive semi-definite matrices, $\|\cdot\|_2 = \lambda_{\max}(\cdot)$, the largest eigenvalue.

7.1 CONSISTENCY OF OLS SIEVE ESTIMATORS

The proof of Theorem 1 makes use of the next lemma (proved in the appendix). Let $\Sigma_k := (r_{|i-j|})_{k \times k}$, with $r_{|i-j|} := \sum_{s=0}^{\infty} \gamma_s \gamma_{s+|i-j|}$; under Assumption 1, the eigenvalues of Σ_k are bounded and bounded away from zero as $k \rightarrow \infty$ (see Berk, 1974, and the related discussion of Σ preceding Lemma 1).

LEMMA 2 *Under Assumption 1 and the condition $k^2/T + 1/k \rightarrow 0$ as $T \rightarrow \infty$, for every $\epsilon > 0$,*

- a. $S_{00}^k := \sum_{t=k+1}^T \mathbf{X}_{t-1}^k (\mathbf{X}_{t-1}^k)'$ has $\|S_{00}^k - \Sigma_k \sigma_T^2\|_2 = O_P(l_T \tilde{a}_T) \max\{k^\epsilon a_k, k\}$, where $\sigma_T^2 := \sum_{t=k+1}^T \varepsilon_t^2$, $l_T = 1$ for $\alpha \neq 1$ and l_T is slowly varying for $\alpha = 1$; Moreover, $(S_{00}^k)^{-1}$ exists with probability approaching one and $\|(S_{00}^k)^{-1} - \Sigma_k^{-1} \sigma_T^{-2}\|_2 = O_P(l_T \tilde{a}_T a_T^{-4}) \max\{k^\epsilon a_k, k\}$.
- b. $S_{0\varepsilon}^k := \sum_{t=k+1}^T \mathbf{X}_{t-1}^k \varepsilon_{t,k}$ satisfies $\|S_{0\varepsilon}^k - \sum_{t=k+1}^T \mathbf{X}_{t-1}^k \varepsilon_t\| = o_P(a_T^{1-\zeta}) + O_P(a_T^2) \sum_{j=k+1}^\infty |\beta_j|$ and $\|S_{0\varepsilon}^k\| = o_P(k^\epsilon a_k l_T \tilde{a}_T) + O_P(a_T^2) \sum_{j=k+1}^\infty |\beta_j|$ with $\zeta > 0$ sufficiently small and l_T as in (a).

PROOF OF THEOREM 1. From $\|\hat{\beta}_k - \beta_k\| = \|(S_{00}^k)^{-1} S_{0\varepsilon}^k\| \leq \|(S_{00}^k)^{-1}\|_2 \|S_{0\varepsilon}^k\|$ and the triangle inequality we obtain that, for $\epsilon > 0$,

$$\begin{aligned} \|\hat{\beta}_k - \beta_k\| &\leq \left[\{\lambda_{\min}(\Sigma_k)\}^{-1} \sigma_T^{-2} + \|(S_{00}^k)^{-1} - \Sigma_k^{-1} \sigma_T^{-2}\|_2 \right] \|S_{0\varepsilon}^k\| \\ &= O_P(a_T^{-2}) \left[o_P(k^\epsilon a_k l_T \tilde{a}_T) + O_P(a_T^2) \sum_{j=k+1}^\infty |\beta_j| \right] \\ &= O_P(a_k a_T^{\epsilon-1}) + O_P\left(\sum_{j=k+1}^\infty |\beta_j| \right) = o_P(1) \end{aligned} \quad (10)$$

using Lemma 2(a,b), the stochastic boundedness of $a_T^2 \sigma_T^{-2}$ (which converges weakly to an a.s. finite r.v.), the convergence of $\sum_{j=1}^\infty |\beta_j|$ and the condition $k^2/T + 1/k \rightarrow 0$. \square

7.2 ASYMPTOTIC α -STABILITY

As the row dimension m of the restriction design matrix L is fixed, it is enough to provide proofs for $m = 1$ (in the case of limiting distributions, by the Cramér-Wold device). Thus, $L = (l_1, l_2, \dots)$ is $1 \times \infty$ in this section.

First, using estimates of the decay rates of the off-diagonal elements of Σ and Σ^{-1} , we discuss the well-definition of the random series in Lemma 1 and its proof. As assumed in that lemma, let $\delta' \in (\delta, \frac{2\alpha}{2+\alpha})$ be such that $\sum_{j=1}^\infty j^s |l_j|^{\delta'} < \infty$.

Regarding Σ , the estimate $r_i \leq c(1+i)^{-2/\delta}$ for some $c > 0$, δ as in Assumption 1(b) and all $i \in \mathbb{N}$ is implied by the convergence of the series $\sum_{i=1}^\infty i^{2/\delta} |r_i|$ which is straightforward to establish under Assumption 1(b). This estimate of r_i implies that $\Sigma \in Q_{2/\delta}$, an algebra studied by Jaffard (1990), and by his Proposition 3, also $\Sigma^{-1} \in Q_{2/\delta}$. Equivalently, if $\Sigma^{-1} =: (s_{ij})_{i,j \in \mathbb{N}}$, then there exists a $c' > 0$ such that $|s_{ij}| \leq c'(1+|i-j|)^{-2/\delta}$ ($i, j \in \mathbb{N}$). As a consequence, for $L\Sigma^{-1} =: (\tilde{l}_1, \tilde{l}_2, \dots)$, $s \in \{0, 1\}$ and δ' as previously, we find that

$$\sum_{i=1}^\infty i^s |\tilde{l}_i|^{\delta'} \leq \sum_{i=1}^\infty i^s \sum_{j=1}^\infty |s_{ji}|^{\delta'} |l_j|^{\delta'} \leq (c')^{\delta'} \sum_{j=1}^\infty \left[\sum_{i=1}^\infty \frac{i^s}{j^s} (1+|i-j|)^{-\frac{2\delta'}{\delta}} \right] j^s |l_j|^{\delta'},$$

where

$$\begin{aligned} \sum_{i=1}^\infty \frac{i^s}{j^s} (1+|i-j|)^{-\frac{2\delta'}{\delta}} &= \sum_{i=1}^j \frac{i^s}{j^s} (1+|i-j|)^{-\frac{2\delta'}{\delta}} + \sum_{i=j+1}^\infty \frac{i^s}{j^s} (1+|i-j|)^{-\frac{2\delta'}{\delta}} \\ &< \sum_{i=1}^j i^{-\frac{2\delta'}{\delta}} + \sum_{i=1}^\infty \frac{(i+j)^s}{j^s} i^{-\frac{2\delta'}{\delta}} < 3 \sum_{i=1}^\infty i^{s-\frac{2\delta'}{\delta}} < \infty \end{aligned}$$

because $\delta' \in (\delta, 1)$. Hence, with $c_s'' := 3(c')^{\delta'} \sum_{i=1}^\infty i^{s-2\delta'/\delta} < \infty$, it holds that $\sum_{i=1}^\infty i^s |\tilde{l}_i|^{\delta'} < c_s'' \sum_{j=1}^\infty j^s |l_j|^{\delta'}$, and further, $\sum_{i=1}^\infty i^s |\tilde{l}_i|^{\delta'} < \infty$ because $\sum_{j=1}^\infty j^s |l_j|^{\delta'} < \infty$. Finally, regarding

A_j , for $s \in \{0, 1\}$ and δ' as previously,

$$\begin{aligned} \sum_{j=1}^{\infty} j^s |A_j|^{\delta'} &\leq \sum_{j=1}^{\infty} \sum_{i=1}^j j^s |\tilde{l}_i|^{\delta'} |\gamma_{j-i}|^{\delta'} \leq 2 \sum_{j=1}^{\infty} \sum_{i=1}^j \{i^s |\tilde{l}_i|^{\delta'}\} \{(j-i+1)^s |\gamma_{j-i}|^{\delta'}\} \\ &\leq 2 \left\{ \sum_{i=1}^{\infty} i^s |\tilde{l}_i|^{\delta'} \right\} \left\{ \sum_{j=0}^{\infty} (j+1)^s |\gamma_j|^{\delta'} \right\}, \end{aligned}$$

so $\sum_{j=1}^{\infty} j^s |A_j|^{\delta'} < \infty$ holds given that $\sum_{i=1}^{\infty} i^s |\tilde{l}_i|^{\delta'} < \infty$ and $\sum_{j=1}^{\infty} j^s |\gamma_j|^{\delta'} < \infty$. This guarantees that the series below are absolutely convergent a.s. (with $s = 0$) and asymptotic results of Davis and Resnick can be invoked (with $s = 1$, for use in the proof of Theorem 2).

PROOF OF LEMMA 1. Let $\tilde{L}_k := (\tilde{l}_1, \tilde{l}_2, \dots, \tilde{l}_k) = (L\Sigma^{-1})_k$ consist of the first k entries of $L\Sigma^{-1}$. Then $\hat{\beta}_k - \beta_k = (S_{00}^k)^{-1} S_{0\varepsilon}^k$ satisfies

$$|L_k(\hat{\beta}_k - \beta_k) - \sigma_T^{-2} \tilde{L}_k \sum_{t=k+1}^T \mathbf{X}_{t-1}^k \varepsilon_t| \leq \|L_k\| (B_1 + B_2) + B_3, \quad (11)$$

where $\|L_k\|^2 \leq \sum_{i=1}^{\infty} l_i^2 < \infty$ for all k , and B_i ($i = 1, 2, 3$) are defined next and shown to be $o_P(a_T^{-2} \tilde{a}_T)$ provided $k^3/T + 1/k \rightarrow 0$. First,

$$B_1 := \|\hat{\beta}_k - \beta_k - (S_{00}^k)^{-1} \sum_{t=k+1}^T \mathbf{X}_{t-1}^k \varepsilon_t\| \leq \|(S_{00}^k)^{-1}\|_2 \|S_{0\varepsilon}^k - \sum_{t=k+1}^T \mathbf{X}_{t-1}^k \varepsilon_t\|,$$

where $\|(S_{00}^k)^{-1}\|_2 = O_P(a_T^{-2})$ as in (10). Thus, using also Lemma 2(b), $B_1 = o_P(a_T^{-1}) + O_P(1) \sum_{j=k+1}^{\infty} |\beta_j| = o_P(a_T^{-1}) = o_P(a_T^{-2} \tilde{a}_T)$, given that $a_T \sum_{j=k+1}^{\infty} |\beta_j| \rightarrow 0$. Second, by Lemma 2(a) and because $\|\sum_{t=k+1}^T \mathbf{X}_{t-1}^k \varepsilon_t\| = o_P(k^\epsilon a_k l_T \tilde{a}_T)$ for all $\epsilon > 0$ (see the proof of Lemma 2(b)), it holds that

$$B_2 := \|(S_{00}^k)^{-1} - \Sigma_k^{-1} \sigma_T^{-2}\|_2 \left\| \sum_{t=k+1}^T \mathbf{X}_{t-1}^k \varepsilon_t \right\| = o_P(\tilde{a}_T^2 a_T^{-4} l_T a_k k^\epsilon \max\{a_k, k\}),$$

using the property that multiplication preserves slow variation. Under $k^3/T \rightarrow 0$ it is checked directly that $\tilde{a}_T^2 a_T^{-4} l_T k^\epsilon = o(a_T^{\epsilon-2})$ for all $\epsilon > 0$ and that $a_T^{\epsilon-2} a_k \max\{a_k, k\} = o(a_T^{-2} \tilde{a}_T)$ for small enough $\epsilon > 0$, so $B_2 = o_P(a_T^{-2} \tilde{a}_T)$. Third,

$$B_3 := \sigma_T^{-2} \|(L_k \Sigma_k^{-1})^\infty - L \Sigma^{-1}\|_2 \left\| \sum_{t=k+1}^T (\mathbf{X}_{t-1}^k)^\infty \varepsilon_t \right\|,$$

where $(\cdot)^\infty$ denotes the infinite sequence (or infinite matrix) obtained from a vector (resp. a matrix) by appending a tail of zeroes (resp. in both dimensions), and the norm is in ℓ_2 (resp. its dual space) in order to comply with the notation of Theorem 3.1 of Strohmer (2002); that theorem ensures the estimate $\|(L_k \Sigma_k^{-1})^\infty - L \Sigma^{-1}\|_2 = O(k^{1/2-s})$ provided that $r_i \leq c(1+i)^{-s}$ and $l_i \leq c(1+i)^{-s}$ for some $s > 1$, $c > 0$ and all $i \in \mathbb{N}$. Under Assumption 1(b), $r_i \leq c(1+i)^{-s}$ was shown above to hold for $s = 2/\delta > 1/2 + 1/\alpha$ and some $c > 0$. As, under the hypotheses of Lemma 1, also $l_i \leq c(1+i)^{-s}$ ($i \in \mathbb{N}$) for some $s > 1/2 + 1/\alpha$, $c > 0$, we can define a new $s > 1/2 + 1/\alpha$ such that $\|(L_k \Sigma_k^{-1})^\infty - L \Sigma^{-1}\|_2 = O(k^{1/2-s})$ does hold. Using also that $\|\sum_{t=k+1}^T (\mathbf{X}_{t-1}^k)^\infty \varepsilon_t\| = \|\sum_{t=k+1}^T \mathbf{X}_{t-1}^k \varepsilon_t\| = o_P(k^\epsilon a_k l_T \tilde{a}_T)$ for all $\epsilon > 0$, we find the product of norms in the definition of B_3 to be $o_P(k^{1/2-s+\epsilon} a_k l_T \tilde{a}_T) = o_P(k^{-\omega} l_T \tilde{a}_T)$ for some $\omega > 0$ defined by fixing a sufficiently small $\epsilon > 0$. For $\alpha \neq 1$ (and $l_T = 1$) this

magnitude order is $o_P(\tilde{a}_T)$, whereas for $\alpha = 1$ the extra assumption that k grows faster than any slowly varying function of T yields the same magnitude order, so $B_3 = o_P(a_T^{-2}\tilde{a}_T)$ because $\sigma_T^{-2} = O_P(a_T^{-2})$. Hence, from (11),

$$L_k(\hat{\beta}_k - \beta_k) = \sigma_T^{-2}\tilde{L}_k \sum_{t=k+1}^T \mathbf{X}_{t-1}^k \varepsilon_t + o_P(a_T^{-2}\tilde{a}_T). \quad (12)$$

Next, define

$$J_1 := \sum_{j=1}^{\infty} \left(\sum_{i=k+1}^j \tilde{l}_i \gamma_{j-i} \right) \sum_{t=k+1}^T \varepsilon_{t-j} \varepsilon_t \mathbb{I}_{|\varepsilon_{t-j} \varepsilon_t| > \tilde{a}_T}$$

and

$$J_2 := \sum_{j=1}^{\infty} \left(\sum_{i=k+1}^j \tilde{l}_i \gamma_{j-i} \right) \sum_{t=k+1}^T (\varepsilon_{t-j} \varepsilon_t \mathbb{I}_{|\varepsilon_{t-j} \varepsilon_t| \leq \tilde{a}_T} - \mu_T).$$

Then we can write

$$\begin{aligned} \tilde{L}_k \sum_{t=k+1}^T (\mathbf{X}_{t-1}^k \varepsilon_t - \mathbf{u}_k \mu_T \gamma(1)) &= \sum_{j=1}^{\infty} \left(\sum_{i=1}^{\min(k,j)} \tilde{l}_i \gamma_{j-i} \right) \sum_{t=k+1}^T (\varepsilon_{t-j} \varepsilon_t - \mu_T) \\ &= \sum_{j=1}^{\infty} A_j \sum_{t=k+1}^T (\varepsilon_{t-j} \varepsilon_t - \mu_T) + J_1 + J_2. \end{aligned} \quad (13)$$

First observe that $J_1 = o_P(\tilde{a}_T)$, since

$$\begin{aligned} \mathbb{E} |\tilde{a}_T^{-1} J_1|^{\delta'} &\leq a_T^{-\delta'} T \mathbb{E} (|\varepsilon_1 \varepsilon_2|^{\delta'} \mathbb{I}_{|\varepsilon_1 \varepsilon_2| > \tilde{a}_T}) \sum_{j=1}^{\infty} \left| \sum_{i=k+1}^j \tilde{l}_i \gamma_{j-i} \right|^{\delta'} \\ &\leq O(1) \left(\sum_{j=1}^{\infty} |\gamma_j|^{\delta'} \right) \left(\sum_{i=k+1}^j |\tilde{l}_i|^{\delta'} \right) = o(1) \end{aligned}$$

by Karamata's theorem [KT] and the fact that $\sum_{i=k+1}^{\infty} |\tilde{l}_i|^{\delta'} \rightarrow 0$ as $k \rightarrow \infty$. Second, $J_2 = o_P(\tilde{a}_T)$, since

$$\begin{aligned} \mathbb{E} J_2^2 &= \sum_{j,h=1}^{\infty} \left(\sum_{i=k+1}^j \tilde{l}_i \gamma_{j-i} \right) \left(\sum_{i=k+1}^h \tilde{l}_i \gamma_{h-i} \right) \\ &\quad \times \sum_{t,s=k+1}^T \mathbb{E} \{ (\varepsilon_{t-j} \varepsilon_t \mathbb{I}_{|\varepsilon_{t-j} \varepsilon_t| \leq \tilde{a}_T} - \mu_T) (\varepsilon_{s-h} \varepsilon_s \mathbb{I}_{|\varepsilon_{s-h} \varepsilon_s| \leq \tilde{a}_T} - \mu_T) \} \\ &\leq 4T \mathbb{E} (\varepsilon_1^2 \varepsilon_2^2 \mathbb{I}_{|\varepsilon_1 \varepsilon_2| \leq \tilde{a}_T}) \left(\sum_{j=1}^{\infty} |\gamma_j|^2 \right) \left(\sum_{i=k+1}^{\infty} |\tilde{l}_i|^2 \right) = o(\tilde{a}_T^2) \end{aligned}$$

by KT and because $\sum_{i=k+1}^{\infty} |\tilde{l}_i| \rightarrow 0$ as $k \rightarrow \infty$. The lemma then follows by combining (12) and (13) with $J_1 + J_2 = o_P(\tilde{a}_T)$. \square

PROOF OF THEOREM 2. Given that $a_k/a_T = o(1)$ and $\tilde{a}_k/\tilde{a}_T = o(1)$ as $T \rightarrow \infty$, and $\sum_{j=1}^{\infty} j |A_j|^{\delta'} < \infty$ by the previous argument, it follows respectively from the proof of Theorem 4.4 of Davis and Resnick (1986) and from their Theorem 3.5 in (1985b) that

$$\left(a_T^{-2} \sum_{t=k+1}^T \varepsilon_t^2, \tilde{a}_T^{-1} \sum_{j=1}^{\infty} A_j \left(\sum_{t=k+1}^T \varepsilon_{t-j} \varepsilon_t - \mu_T \right) \right) \xrightarrow{w} \left(S, \sum_{j=1}^{\infty} A_j S_j \right),$$

with the limit distribution respectively as in the two parts of Theorem 2. This convergence and Lemma 1 prove Theorem 2. \square

7.3 BOOTSTRAP APPROXIMATIONS

7.3.1 NOTATION AND PREPARATORY RESULTS

Without loss of generality, in this section we set $X_t^* = 0$, $t = 1, \dots, k$. Let \hat{V}_k be the $k \times k$ matrix $\hat{V}_k := (\hat{\beta}_k, \mathbf{u}_1, \dots, \mathbf{u}_{k-1})'$, where \mathbf{u}_i is the i th canonical basis vector in \mathbb{R}^k , and let $\hat{\gamma}_{j:k} := \hat{V}_k^j \mathbf{u}_1 = (\hat{\gamma}_j, \dots, \hat{\gamma}_{j-k+1})'$, $\hat{\gamma}_i := 0$ ($i < 0$). Then, $\mathbf{X}_t^{*k} = \sum_{j=0}^{t-k-1} \hat{\gamma}_{j:k} \varepsilon_{t-j}^*$, $t = k+1, \dots, T$.

Further, as a benchmark, we introduce the (infeasible) bootstrap errors $\varepsilon_t^\dagger := \varepsilon_{\pi(t)} w_t$ ($t = k+1, \dots, T$), which are a transformation of the true errors ε_t instead of the residuals $\hat{\varepsilon}_t$, with π and $\{w_t\}_{t=k+1}^\infty$ defined respectively as in the wild, permutations or permuted wild bootstrap. Associated with ε_t^\dagger we define the infeasible bootstrap sample $X_t^\dagger = 0$ ($t = 1, \dots, k$) and $\mathbf{X}_t^{\dagger k} = \sum_{j=0}^{t-k-1} \gamma_{j:k} \varepsilon_{t-j}^\dagger$, $t = k+1, \dots, T$, where $\mathbf{X}_t^{\dagger k} := (X_t^\dagger, \dots, X_{t-k+1}^\dagger)'$, $\gamma_{j:k} := (\gamma_j, \dots, \gamma_{j-k+1})'$, $\gamma_i := 0$ ($i < 0$), as well as the product moments matrices $S_{00}^{\dagger k} := \sum_{t=k+1}^T \mathbf{X}_{t-1}^{\dagger k} (\mathbf{X}_{t-1}^{\dagger k})'$ and $S_{0\varepsilon}^{\dagger k} := \sum_{t=k+1}^T \mathbf{X}_{t-1}^{\dagger k} \varepsilon_{t,k}^\dagger$, where $\varepsilon_{t,k}^\dagger := \varepsilon_t^\dagger + \rho_{t,k}^\dagger$, $\rho_{t,k}^\dagger := \sum_{i=k+1}^{t-k-1} \beta_i X_{t-i}^\dagger$. Equivalently,

$$X_t^\dagger = \begin{cases} 0 & t = 1, \dots, k \\ \beta_k' \mathbf{X}_{t-1}^{\dagger k} + \varepsilon_{t,k}^\dagger & t = k+1, \dots, T \end{cases}.$$

In order to prove Theorem 3 we will need the following Lemma 3 (proved in the appendix). We denote by P^\dagger probability conditional on $\{\varepsilon_t\}_{t=-\infty}^T$ (equivalently, on $\{\varepsilon_t\}_{t=-\infty}^T$ and the data, as the latter are a measurable function of $\{\varepsilon_t\}_{t=-\infty}^T$).

LEMMA 3 *Under Assumption 1 and the conditions $k^4/T + 1/k \rightarrow 0$, $a_T \sum_{i=k+1}^\infty |\beta_i| \rightarrow 0$ as $T \rightarrow \infty$, it holds in P -probability that:*

- $\|S_{00}^{*k} - S_{00}^{\dagger k}\| = o_{P^\dagger}(ka_k a_T^{1+\epsilon})$ for all $\epsilon > 0$ and $\lambda_{\min}^{-1}(a_T^{-2} S_{00}^{*k}) = O_{P^\dagger}(1)$ in P -probability.
- If π is the identity, then $\|S_{0\varepsilon}^{*k} - S_{0\varepsilon}^{\dagger k} - \sigma_1\| = o_{P^\dagger}(a_T^1)$, where $\sigma_1 := \sum_{t=k+1}^T \mathbf{X}_{t-1}^{*k} (\hat{\varepsilon}_t - \varepsilon_{\pi(t),k}) w_t$. If π is a random permutation [r.p.], then $\|S_{0\varepsilon}^{*k} - S_{0\varepsilon}^{\dagger k}\| = o_{P^\dagger}(T^{\epsilon-1/2} k^{1/2} a_k a_T)$ for all $\epsilon > 0$.
- $\|S_{0\varepsilon}^{\dagger k}\| = O_{P^\dagger}(a_k^{1+\epsilon} \tilde{a}_T)$ for π equal to the identity and all $\epsilon > 0$, and $\|S_{0\varepsilon}^{\dagger k}\| = O_{P^\dagger}(h_{Tk})$ for an r.p. π , with $h_{Tk} = \min\{\frac{k^{1/2}}{T^{1/2}} a_T^2, \frac{k}{T} \max\{T^2, a_T^2 l_T^2\}\}$ and l_T as in Lemma 2.

7.3.2 PROOF OF THEOREM 3

Let the bootstrap statistic and its corrected version be $\tau^* := a_T^2 \tilde{a}_T^{-1} L_k(\hat{\beta}_k^* - \hat{\beta}_k)$ and $\tau_c^* := a_T^2 \tilde{a}_T^{-1} L_k\{(\hat{\beta}_k^* - \hat{\beta}_k) - (S_{00}^{*k})^{-1} \sigma_1\}$, where $\sigma_1 = \sum_{t=k+1}^T \mathbf{X}_{t-1}^{*k} (\hat{\varepsilon}_{\pi(t)} - \varepsilon_{\pi(t),k}) w_t$. We need to evaluate the Lévy distance between the distribution of τ^* and τ_c^* conditional of the data and three conditional distributions of $\tau := a_T^2 \tilde{a}_T^{-1} L_k(\hat{\beta}_k - \beta_k)$. To this end, we introduce some auxiliary r.v.'s and evaluate sequentially several distances involving them as well as τ^* , τ_c^* and τ , such that our desired evaluation then follows by the triangle inequality. The auxiliary r.v.'s are $\tau^\dagger := a_T^2 \tilde{a}_T^{-1} L_k(S_{00}^{\dagger k})^{-1} S_{0\varepsilon}^{\dagger k}$, $\check{\tau} := a_T^2 \tilde{a}_T^{-1} L_k(\check{S}_{00}^k)^{-1} \check{S}_{0\varepsilon}^k$ and $\tau^\pi := a_T^2 \tilde{a}_T^{-1} L_k(S_{00}^{\pi k})^{-1} S_{0\varepsilon}^{\pi k}$, where we define $\check{S}_{00}^k := \sum_{t=k+2}^T \check{\mathbf{X}}_{t-1}^k (\check{\mathbf{X}}_{t-1}^k)'$ and $\check{S}_{0\varepsilon}^k := \sum_{t=k+2}^T \check{\mathbf{X}}_{t-1}^k \varepsilon_{\pi(t)}$ with $\check{\mathbf{X}}_{t-1}^k := \sum_{j=0}^{t-k-2} \gamma_{j:k} \varepsilon_{\pi(t-j-1)}$, while $S_{00}^{\pi k} := \sum_{t=k+2}^T \mathbf{X}_{t-1}^{\pi k} (\mathbf{X}_{t-1}^{\pi k})'$ and $S_{0\varepsilon}^{\pi k} := \sum_{t=k+2}^T \mathbf{X}_{t-1}^{\pi k} (\varepsilon_{\pi(t)} + \rho_{t,k}^\pi)$ with $\mathbf{X}_{t-1}^{\pi k} := \sum_{j=0}^{t-k-2} \gamma_{j:k} \varepsilon_{\pi(t-j-1)} + \sum_{j=t-k}^\infty \gamma_{j:k} \varepsilon_{t-j}$ and finally $\rho_{t,k}^\pi := \sum_{i=k+1}^\infty \beta_i (\sum_{m=0}^{t-k-i-1} \gamma_m \varepsilon_{\pi(t-m-i)} + \sum_{m=t-k-i}^\infty \gamma_m \varepsilon_{t-m-i})$. The sequential distances are as follows.

1. The bootstrap statistics τ^* and τ_c^* , as measurable functions of the data, π and $\{w_t\}_{t=k+1}^T$, have the same distribution conditional on the data. Specifically, conditional on the data and all past $\{\varepsilon_t\}_{t=-\infty}^T$ it holds that $\rho_{1c} := \rho_L(\mathcal{L}^*(\tau_c^*), \mathcal{L}^\dagger(\tau_c^*)) = 0$ and $\rho_1 := \rho_L(\mathcal{L}^*(\tau^*), \mathcal{L}^\dagger(\tau^*)) = 0$, where ρ_L denotes Lévy distance, \mathcal{L} stands for law, the $*$ superscript for conditioning on the data, and the \dagger superscript for conditioning on the data and $\{\varepsilon_t\}_{t=-\infty}^T$.

2. If π is the identity, then $\tau_c^* = a_T^2 \tilde{a}_T^{-1} L_k(S_{00}^{*k})^{-1} (S_{0\varepsilon}^{*k} - \sigma_1) = \tau^\dagger + o_{P^\dagger}(1)$ in P -probability (proved below), whereas if π is an r.p., also $\tau^* = \tau^\dagger + o_{P^\dagger}(1)$ in P -probability independently of the specification of $\{w_t\}_{t=k+1}^T$ (proved below). Hence,

$$\rho_{2c} := \rho_L(\mathcal{L}^\dagger(\tau_c^*), \mathcal{L}^\dagger(\tau^\dagger)) = o_P(1), \quad \rho_2 := \rho_L(\mathcal{L}^\dagger(\tau^*), \mathcal{L}^\dagger(\tau^\dagger)) = o_P(1).$$

3(a). Under bootstrap schemes \mathbf{w}_R and symmetry of ε_t , it holds that $\rho_3^{|\varepsilon|} := \rho_L(\mathcal{L}^\dagger(\tau^\dagger), \mathcal{L}^{|\varepsilon|}(\check{\tau})) = 0$, where the $|\varepsilon|$ subscript denotes conditioning on $\{|\varepsilon_t|\}_{t=-\infty}^T$.

3(b). Under scheme $(\boldsymbol{\pi}_R, \mathbf{w}_1)$, $\tau^\dagger = \check{\tau}$ so $\rho_3^\dagger := \rho_L(\mathcal{L}^\dagger(\tau^\dagger), \mathcal{L}^\dagger(\check{\tau})) = 0$.

4(a). Under symmetry of ε_t , $\check{\tau} = \tau^\pi + o_{P^{|\varepsilon|}}(1)$ in P -probability (discussed below), resulting in $\rho_L(\mathcal{L}^{|\varepsilon|}(\check{\tau}), \mathcal{L}^{|\varepsilon|}(\tau^\pi)) = o_P(1)$. Two conclusions follow.

Where π is the identity, it holds that $\tau^\pi = \tau$, so the previous convergence becomes $\rho_4^{|\varepsilon|} := \rho_L(\mathcal{L}^{|\varepsilon|}(\check{\tau}), \mathcal{L}^{|\varepsilon|}(\tau)) = o_P(1)$.

Instead, where π is an r.p., τ conditional on $\{|\varepsilon_t|\}_{t=-\infty}^k$ and the order statistics of $\{|\varepsilon_t|\}_{t=k+1}^T$ is distributed like τ^π conditional on $\{|\varepsilon_t|\}_{t=-\infty}^T$, so now $\rho_4^{|\varepsilon|} := \rho_L(\mathcal{L}^{|\varepsilon|}(\check{\tau}), \mathcal{L}^{|\varepsilon|}(\tau)) = o_P(1)$, with $|\varepsilon|$ standing for conditioning on $\{|\varepsilon_t|\}_{t=-\infty}^k$ and the order statistics of $\{|\varepsilon_t|\}_{t=k+1}^T$.

4(b). Generally, $\check{\tau} = \tau^\pi + o_{P^\dagger}(1)$ in P -probability (discussed below). As τ conditional on $\{\varepsilon_t\}_{t=-\infty}^k$ and the order statistics of $\{\varepsilon_t\}_{t=k+1}^T$ is distributed like τ^π conditional on $\{\varepsilon_t\}_{t=-\infty}^T$ (equivalently, under P^\dagger), it follows that $\rho_4^{\mathbf{e}} := \rho_L(\mathcal{L}^\dagger(\check{\tau}), \mathcal{L}^{\mathbf{e}}(\tau)) = o_P(1)$, with \mathbf{e} standing for conditioning on $\{\varepsilon_t\}_{t=-\infty}^k$ and the order statistics of $\{\varepsilon_t\}_{t=k+1}^T$.

Next we combine the previous evaluations. First, we can conclude that, for π equal to the identity (scheme $\boldsymbol{\pi}_{id}$, wild bootstrap),

$$\rho_L(\mathcal{L}^*(\tau_c^*), \mathcal{L}^{|\varepsilon|}(\tau)) \leq \rho_{1c} + \rho_{2c} + \rho_3^{|\varepsilon|} + \rho_4^{|\varepsilon|} = o_P(1),$$

which is equivalent to the convergence in Theorem 3(a). On the other hand, for an r.p. π ,

$$\begin{aligned} \rho_L(\mathcal{L}^*(\tau^*), \mathcal{L}^{\mathbf{e}}(\tau)) &\leq \rho_1 + \rho_2 + \rho_3^\dagger + \rho_4^{\mathbf{e}} = o_P(1) \text{ for } (\boldsymbol{\pi}_R, \mathbf{w}_1), \\ \rho_L(\mathcal{L}^*(\tau^*), \mathcal{L}^{|\varepsilon|}(\tau)) &\leq \rho_1 + \rho_2 + \rho_3^{|\varepsilon|} + \rho_4^{|\varepsilon|} = o_P(1) \text{ for } (\boldsymbol{\pi}_R, \mathbf{w}_R); \end{aligned}$$

hence, Theorem 3(b,c).

It remains to complete steps 2 and 4 outlined above.

Step 2. Let $\sigma_1^{id} := \mathbb{I}_{\pi=id}\sigma_1$. The next evaluation is valid for $L_k \neq 0$ of type $m \times k$, $m \in \mathbb{N}$:

$$\begin{aligned} &\|L_k\|^{-1} \|L_k(S_{00}^{*k})^{-1} (S_{0\varepsilon}^{*k} - \sigma_1^{id}) - L_k(S_{00}^{\dagger k})^{-1} S_{0\varepsilon}^{\dagger k}\| \\ &\leq \|(S_{00}^{*k})^{-1} - (S_{00}^{\dagger k})^{-1}\| \|S_{0\varepsilon}^{*k} - \sigma_1^{id}\| + \|(S_{00}^{\dagger k})^{-1}\|_2 \|S_{0\varepsilon}^{*k} - \sigma_1^{id} - S_{0\varepsilon}^{\dagger k}\| \\ &\leq \frac{\|(S_{00}^{\dagger k})^{-1}\|_2^2 \|S_{00}^{*k} - S_{00}^{\dagger k}\|}{1 - \|(S_{00}^{\dagger k})^{-1}\|_2 \|S_{00}^{*k} - S_{00}^{\dagger k}\|} (\|S_{0\varepsilon}^{\dagger k}\| + \|S_{0\varepsilon}^{*k} - \sigma_1^{id} - S_{0\varepsilon}^{\dagger k}\|) \\ &\quad + \|(S_{00}^{\dagger k})^{-1}\|_2 \|S_{0\varepsilon}^{*k} - \sigma_1^{id} - S_{0\varepsilon}^{\dagger k}\| \end{aligned}$$

with P^\dagger -probability approaching 1 in P -probability, as $\|(S_{00}^{\dagger k})^{-1}\|_2 \|S_{00}^{*k} - S_{00}^{\dagger k}\| = o_{P^\dagger}(1)$ in P -probability by Lemma 3. Using again Lemma 3 and the conditions $k^4/T \rightarrow 0$ (for $\boldsymbol{\pi}_{id}$)

and $k^5/T \rightarrow 0$, $k^{1+2/\alpha+\zeta}/T \rightarrow 0$ (for π_R and some $\zeta > 0$) it follows that for small enough $\epsilon > 0$,

$$\begin{aligned}
& \|L_k\|^{-1} |L_k(S_{00}^{*k})^{-1}(S_{0\epsilon}^{*k} - \sigma_1^{id}) - L_k(S_{00}^{\dagger k})^{-1}S_{0\epsilon}^{\dagger k}| \\
& \leq \frac{o_{P^\dagger}(ka_k a_T^{\epsilon-3})}{1 + o_{P^\dagger}(1)} \left(\mathbb{I}_{\pi=id} a_k a_T^{1+\epsilon} + \mathbb{I}_{\pi=r.p.} \{h_{Tk} + T^{\epsilon-1/2} k^{1/2} a_k a_T\} \right) \\
& \quad + a_T^{-2} o_{P^\dagger}(\mathbb{I}_{\pi=id} a_T + \mathbb{I}_{\pi=r.p.} T^{\epsilon-1/2} k^{1/2} a_k a_T) \\
& = o_{P^\dagger}(a_T^{-1}) \text{ in } P\text{-probability}
\end{aligned}$$

for all the three bootstrap schemes, from where step 2 follows.

Step 4. This step is analogous to step 2, prepared by Lemma 3's estimates involving ρ , with $\text{sgn } \varepsilon_t$ playing the role of w_t . \square

A APPENDIX: EXTENDED PROOFS

A.1 INTRODUCTION

This appendix contains additional theoretical results and proofs for the theory stated in the paper. The appendix is organized as follows. Section A.2 provides a lemma with two tail inequalities regarding the series of the coefficients from the AR(∞) representations. Section A.3 reports the proof of Lemma 2 and corollaries from Section 6. Section A.4 contains proofs of the results given in Section 7.3.1. Finally, Section A.5 discusses the case of multiple restrictions.

A.2 A TAIL INEQUALITY

We first establish two inequalities between the tails of the series of autoregressive coefficients and their powers.

LEMMA A.1 *Under Assumption 1, let $k^2/T + 1/k \rightarrow 0$ as $T \rightarrow \infty$. Then for large T , for η in a sufficiently small left neighborhood of $\alpha \wedge 1 := \min\{\alpha, 1\}$ and for $\zeta > 0$ sufficiently small, it holds that*

$$\tilde{a}_T a_T^{-2} (k \sum_{j=k+1}^{\infty} |\beta_j|^\eta)^{1/\eta} \leq \tilde{a}_T a_T^{-\zeta-2} + \sum_{j=k+1}^{\infty} |\beta_j|. \quad (\text{A.1.1})$$

If $k^3/T + 1/k \rightarrow 0$ as $T \rightarrow \infty$, then also

$$\tilde{a}_T a_T^{-2} (k \sum_{j=k+1}^{\infty} |\beta_j|^\eta)^{1/\eta} \leq \tilde{a}_T a_T^{-9/4} + a_T^{-1/5} \sum_{j=k+1}^{\infty} |\beta_j|. \quad (\text{A.1.2})$$

PROOF. In the case of a finite-order AR representation the inequality is obvious, so we discuss the opposite case.

From $\sum_{j=1}^{\infty} j^{2/\delta} |\beta_j| < \infty$ it follows that $|\beta_j| \leq j^{-2/\delta}$ for large j . For fixed k , the expression $(\sum_{j=k+1}^{\infty} |\beta_j|)^{-\eta} \sum_{j=k+1}^{\infty} |\beta_j|^\eta$ cannot be prolonged by continuity to the zero sequence in ℓ_2 , so we consider separately the sets

$$\begin{aligned}
\mathbb{B}_l & := \{ \{ |\beta_j| \}_{j=k+1}^{\infty} : 0 \leq |\beta_j| \leq a_T^{-\zeta} j^{-2/\delta}, j = k+1, \dots \}, \\
\mathbb{B}_u & := \{ \{ |\beta_j| \}_{j=k+1}^{\infty} : a_T^{-\zeta} j^{-2/\delta} \leq |\beta_j| \leq j^{-2/\delta}, j = k+1, \dots \}.
\end{aligned}$$

Using the upper bound in the standard estimate

$$\frac{(K+1)^{1-s}}{s-1} \leq \sum_{j=K+1}^{\infty} j^{-s} \leq \frac{K^{1-s}}{s-1} \text{ for } s > 1, \quad (\text{A.1.3})$$

we find that on \mathbb{B}_l ,

$$\tilde{a}_T a_T^{-2} (k \sum_{j=k+1}^{\infty} |\beta_j|^\eta)^{1/\eta} \leq C \tilde{a}_T a_T^{-\zeta-2} (k+1)^{\frac{2(\delta-\eta)}{\delta\eta}} = o(\tilde{a}_T a_T^{-\zeta-2})$$

for $T \geq 2$, $\delta < \eta$ and sufficiently small $\zeta > 0$. If \mathbb{B}_u is equipped with the ℓ_2 metric, it becomes a compact in ℓ_2 , for it is closed, bounded and for every $\epsilon > 0$ there exists an $N \in \mathbb{N}$ such that for all $\{|\beta_j|\}_{j=k+1}^{\infty} \in \mathbb{B}_u$ it holds that $\sum_{j=N}^{\infty} \beta_j^2 \leq \sum_{j=N}^{\infty} j^{-4/\delta} < \epsilon$. The expression $(\sum_{j=k+1}^{\infty} |\beta_j|)^{-\eta} \sum_{j=k+1}^{\infty} |\beta_j|^\eta$ defines a continuous real function on \mathbb{B}_u and, hence, attains a maximum there. Let $\{|\beta_j^\#\}_{j=k+1}^{\infty}$ denote a maximizing sequence; by examining directional derivatives, it follows that $|\beta_j^\#|$ ($j = k+1, \dots$) satisfy

$$|\beta_j^\#| = \begin{cases} a_T^{-\zeta} j^{-2/\delta} & \text{if } B^\# < a_T^{-\zeta} j^{-2/\delta} \\ B^\# & \text{if } a_T^{-\zeta} j^{-2/\delta} \leq B^\# < j^{-2/\delta} \\ j^{-2/\delta} & \text{if } j^{-2/\delta} \leq B^\# \end{cases}$$

with $B^\# = \left(\sum_{j=k+1}^{\infty} |\beta_j^\#| / \sum_{j=k+1}^{\infty} |\beta_j^\#|^\eta \right)^{\frac{1}{1-\eta}} \neq 0$. We examine this condition without attempting to find all $|\beta_j^\#|$ exactly.

As $B^\# > 0$ and $j^{-2/\delta}$ is decreasing in j , $|\beta_j^\#| = j^{-2/\delta}$ necessarily holds from some index onwards. Let $K_2 \geq k$ be the smallest natural $\geq k$ such that $|\beta_j^\#| = j^{-2/\delta}$ for $j \geq K_2 + 1$. Then $(K_2 + 1)^{-2/\delta} \leq B^\#$ and, if $K_2 > k$, then $B^\# < K_2^{-2/\delta}$ and $|\beta_j^\#| \neq j^{-2/\delta}$ for $j = k+1, \dots, K_2$.

Still if $K_2 > k$, then either $|\beta_{k+1}^\#| = B^\#$ or $|\beta_{k+1}^\#| = a_T^{-\zeta} j^{-2/\delta} > B^\#$. In the former case it must be that $a_T^{-\zeta} (k+1)^{-2/\delta} \leq B^\#$, so $a_T^{-\zeta} j^{-2/\delta} \leq B^\#$ for all $j \geq k+1$, the value $a_T^{-\zeta} j^{-2/\delta}$ is never taken by $|\beta_j^\#|$ and at K_2 a switch between $B^\#$ and $j^{-2/\delta}$ takes place; define $K_1 = k$ in this case. On the other hand, if $|\beta_{k+1}^\#| = a_T^{-\zeta} (k+1)^{-2/\delta} > B^\#$, let $K_1 < K_2$ be the largest natural j such that $a_T^{-\zeta} j^{-2/\delta} > B^\#$ for $j = k+1, \dots, K_1$. Then at K_1 a switch between $a_T^{-\zeta} j^{-2/\delta}$ and $B^\#$ or $j^{-2/\delta}$ takes place.

Summarizing,

$$|\beta_j^\#| = \begin{cases} a_T^{-\zeta} j^{-2/\delta} & k+1 \leq j \leq K_1 \\ B^\# & K_1+1 \leq j \leq K_2 \\ j^{-2/\delta} & j \geq K_2+1, \dots, \end{cases}$$

with

$$B^\# = \left(\frac{a_T^{-\zeta} \sum_{j=k+1}^{K_1} j^{-2/\delta} + (K_2 - K_1) B^\# + \sum_{j=K_2+1}^{\infty} j^{-2/\delta}}{a_T^{-\zeta\eta} \sum_{j=k+1}^{K_1} j^{-2\eta/\delta} + (K_2 - K_1) B^{\#\eta} + \sum_{j=K_2+1}^{\infty} j^{-2\eta/\delta}} \right)^{\frac{1}{1-\eta}},$$

where the first two conditions may be satisfied by an empty set of j 's. If switches do occur, then $a_T^{-\zeta} (K_1 + 1)^{-2/\delta} \leq B^\# \leq a_T^{-\zeta} K_1^{-2/\delta}$ holds at a switch away from the $a_T^{-\zeta} j^{-2/\delta}$ branch, and $(1 + K_2)^{-2/\delta} \leq B^\# \leq K_2^{-2/\delta}$ at the start of the $j^{-2/\delta}$ branch.

Solving for $B^\#$ in its defining equation gives

$$B^\# = \left(\frac{a_T^{-\zeta} \sum_{j=k+1}^{K_1} j^{-2/\delta} + \sum_{j=K_2+1}^{\infty} j^{-2/\delta}}{a_T^{-\zeta\eta} \sum_{j=k+1}^{K_1} j^{-2\eta/\delta} + \sum_{j=K_2+1}^{\infty} j^{-2\eta/\delta}} \right)^{\frac{1}{1-\eta}},$$

and using (A.1.3), it follows that B^\sharp satisfies

$$\begin{aligned} \frac{a_T^{-\zeta} \{(k+1)^{1-2/\delta} - K_1^{1-2/\delta}\} + (K_2+1)^{1-2/\delta}}{a_T^{-\zeta \eta} (k^{1-2\eta/\delta} - (K_1+1)^{1-2\eta/\delta}) + K_2^{1-2\eta/\delta}} &\leq \frac{2-\delta}{2\eta-\delta} (B^\sharp)^{1-\eta} \\ &\leq \frac{a_T^{-\zeta} k^{1-2/\delta} + K_2^{1-2/\delta}}{a_T^{-\zeta \eta} \{(k+1)^{1-2\eta/\delta} - K_1^{1-2\eta/\delta}\} + (K_2+1)^{1-2\eta/\delta}} \end{aligned} \quad (\text{A.1.4})$$

We examine the implications of this inequality and the switching conditions for subsequential limits. Two cases are possible.

1. If two switches occur, then $K_2/K_1 \sim a_T^{\delta\zeta/2}$ from the switching conditions. Let $a_T^{-\zeta} (k/K_2)^{1-2/\delta} \rightarrow c$ as $T \rightarrow \infty$, possibly along a subsequence; we are looking for the values of c that can occur. Passing to the (subsequential) limit in (A.1.4), it follows that

$$c+1 \leq \frac{2-\delta}{2\eta-\delta} (\lim K_2^{2/\delta} B^\sharp)^{1-\eta} \leq c+1,$$

and since $K_2^{2/\delta} B^\sharp \rightarrow 1$, the unique subsequential limit is $c = 2(1-\eta)/(2\eta-\delta)$, and thus, it is the limit of $a_T^{-\zeta} (k/K_2)^{1-2/\delta}$ as $T \rightarrow \infty$. Further, since $a_T^2 K_1^{2/\delta} B_\# \rightarrow 1$, we find that $K_1 \sim c^{\frac{\delta}{2-\delta}} a_T^{\frac{\zeta\delta^2}{2(2-\delta)}} k$ and $K_2 \sim c^{\frac{\delta}{2-\delta}} a_T^{\frac{\zeta\delta}{2-\delta}} k$. Then

$$\begin{aligned} \frac{(\sum_{j=k+1}^{\infty} |\beta_j|^\eta)^{1/\eta}}{\sum_{j=k+1}^{\infty} |\beta_j|} &= \frac{(a_T^{-\zeta \eta} \sum_{j=k+1}^{K_1} j^{-2\eta/\delta} + (K_2-K_1) B^\sharp + \sum_{j=K_2+1}^{\infty} j^{-2\eta/\delta})^{1/\eta}}{a_T^{-\zeta} \sum_{j=k+1}^{K_1} j^{-2/\delta} + (K_2-K_1) B^\sharp + \sum_{j=K_2+1}^{\infty} j^{-2/\delta}} \\ &\sim \frac{(c_1 a_T^{-\zeta \eta} k^{1-2\eta/\delta} + c_2 a_T^{-\frac{\zeta(2\eta-\delta)}{2-\delta}} k^{1-2\eta/\delta})^{1/\eta}}{c_3 a_T^{-\zeta} k^{1-2/\delta}} \sim c_4 (a_T^{\frac{\zeta\delta}{2-\delta}} k)^{\frac{1-\eta}{\eta}} \end{aligned}$$

for some positive $c_{1,2,3,4}$, and

$$\tilde{a}_T a_T^{-2} \frac{(k \sum_{j=k+1}^{\infty} |\beta_j|^\eta)^{1/\eta}}{\sum_{j=k+1}^{\infty} |\beta_j|} \sim c_4 \tilde{a}_T a_T^{-2} k^{1/\eta} (a_T^{\frac{\zeta\delta}{2-\delta}} k)^{\frac{1-\eta}{\eta}} = o(1)$$

for $k^2/T \rightarrow 0$, η in a sufficiently small left neighbourhood of $\alpha \wedge 1$ and $\zeta > 0$ sufficiently small. The same expression is $o(a_T^{-1/5})$ for $k^3/T \rightarrow 0$ and $\zeta = \frac{1}{4}$.

2. Alternatively, if the value of $a_T^{-\zeta} j^{-2/\delta}$ is not taken by any $|\beta_j^\sharp|$, we are left with

$$\frac{(K_2+1)^{1-2/\delta}}{K_2^{1-2\eta/\delta}} \leq \frac{2-\delta}{2\eta-\delta} (B^\sharp)^{1-\eta} \leq \frac{K_2^{1-2/\delta}}{(K_2+1)^{1-2\eta/\delta}}$$

or equivalently,

$$\left(\frac{2\eta-\delta}{2-\delta}\right)^{\frac{1}{1-\eta}} \left(1 + \frac{1}{K_2}\right)^{\frac{\delta-2}{\delta(1-\eta)}} K_2^{-\frac{2}{\delta}} \leq B^\sharp \leq \left(\frac{2\eta-\delta}{2-\delta}\right)^{\frac{1}{1-\eta}} \left(1 + \frac{1}{K_2}\right)^{\frac{2-\delta}{\delta(1-\eta)}} (K_2+1)^{-\frac{2}{\delta}}.$$

As $(K_2+1)^{-2/\delta} \leq B^\sharp \leq K_2^{-2/\delta}$ should also hold, it follows that

$$\frac{2\eta-\delta}{2-\delta} \left(1 + \frac{1}{K_2}\right)^{\frac{\delta-2}{\delta}} \leq 1 \leq \frac{2\eta-\delta}{2-\delta} \left(1 + \frac{1}{K_2}\right)^{\frac{2-\delta}{\delta}},$$

which is equivalent to $K_2 \leq \left[\{(2-\delta)/(2\eta-\delta)\}^{\frac{\delta}{2-\delta}} - 1\right]^{-1}$ for $\eta \in (\frac{\delta}{2}, 1)$. As this is inconsistent with $K_2 > k \rightarrow \infty$ as $T \rightarrow \infty$, for large T the maximizing sequence is $|\beta_j^\sharp| = j^{-2/\delta}$,

$j \geq k + 1$. Therefore, $\sum_{j=1}^{\infty} j^{2/\delta} |\beta_j| < \infty$ implies for large T that

$$\frac{\sum_{j=k+1}^T |\beta_j|^\eta}{(\sum_{j=k+1}^T |\beta_j|)^\eta} \leq \frac{\sum_{j=k+1}^T j^{-2\eta/\delta}}{(\sum_{j=k+1}^T j^{-2/\delta})^\eta} \leq \frac{\frac{\delta}{2\eta-\delta} k^{1-2\eta/\delta}}{(\frac{\delta}{2-\delta})^\eta (k+1)^{\eta-2\eta/\delta}} \leq ck^{1-\eta}$$

for obvious choices of c , so

$$\tilde{a}_T a_T^{-2} \frac{(k \sum_{j=k+1}^{\infty} |\beta_j|^\eta)^{1/\eta}}{\sum_{j=k+1}^{\infty} |\beta_j|} \leq c^{1/\eta} \tilde{a}_T a_T^{-2} k^{2/\eta-1} = \begin{cases} o(1) & \text{if } k^2/T \rightarrow 0 \\ o(a_T^{-1/5}) & \text{if } k^3/T \rightarrow 0 \end{cases}$$

for η smaller than but close to $\alpha \wedge 1$.

This proves the lemma. \square

A.3 ADDITIONAL PROOFS

Together with the matrix norms $\|\cdot\|_2$ and $\|\cdot\|$ employed in the the paper, here we also use the linear space matrix norms $\|\cdot\|_1 := \sup_{\|x\|_1=1} \|(\cdot)x\|_1$ and $\|\cdot\|_\infty := \sup_{\|x\|_\infty=1} \|(\cdot)x\|_\infty$ induced respectively by the 1 and max vector norms.

A.3.1 PROOF OF LEMMA 2

Regarding S_{00}^k of part (a), we argue first that $\|S_{00}^k \sigma_T^{-2} - \Sigma_k\|_2 = O_P(l_T \tilde{a}_T a_T^{-2}) \max\{k^\epsilon a_k, k\} = o_P(1)$ when $k^2/T \rightarrow 0$. Then $\lambda_{\min}(S_{00}^k \sigma_T^{-2}) \geq \lambda_{\min}(\Sigma_k) - \|S_{00}^k \sigma_T^{-2} - \Sigma_k\|_2 = \lambda_{\min}(\Sigma_k) + o_P(1)$ by Weyl's inequality (Seber, 2008, p.117), so $\lambda_{\min}(S_{00}^k \sigma_T^{-2})$ is bounded away from zero in probability and $(S_{00}^k)^{-1}$ exists with probability approaching one. Further we use the fact that

$$\|(S_{00}^k)^{-1} \sigma_T^2 - \Sigma_k^{-1}\|_2 \leq \frac{\|\Sigma_k^{-1}\|_2^2 \|S_{00}^k \sigma_T^{-2} - \Sigma_k\|_2}{1 - \|\Sigma_k^{-1}\|_2 \|S_{00}^k \sigma_T^{-2} - \Sigma_k\|_2}$$

if $\|\Sigma_k^{-1}\|_2 \|S_{00}^k \sigma_T^{-2} - \Sigma_k\|_2 < 1$. The latter inequality holds with probability approaching one since $\|\Sigma_k^{-1}\|_2$ is bounded as $k \rightarrow \infty$ and $\|S_{00}^k \sigma_T^{-2} - \Sigma_k\|_2 = o_P(1)$, so we can conclude that also

$$\|(S_{00}^k)^{-1} \sigma_T^2 - \Sigma_k^{-1}\|_2 = O_P(l_T \tilde{a}_T a_T^{-2}) \max\{k^\epsilon a_k, k\}.$$

The proof of part (a) is completed observing that $a_T^{-2} \sigma_T^2$ is bounded away from zero in probability as it converges in distribution to an a.s. positive ($\alpha/2$ -stable) r.v.

We present now the evaluation of $\|S_{00}^k \sigma_T^{-2} - \Sigma_k\|_2$. A generic element of S_{00}^k is $\sum_{t=k}^{T-1} X_{t-i} X_{t-j} = c_{ij}^k + \xi_{ij}^{\leq} + \xi_{ij}^{\geq}$ (for $0 \leq i, j \leq k-1$), where $c_{ij}^k := \sum_{t=k}^{T-1} \sum_{v=0}^{\infty} \varepsilon_{t-\max(i,j)-v}^2 \gamma_v \gamma_{v+|j-i|}$ and

$$\xi_{ij}^R := \sum_{t=k}^{T-1} \sum_{u,v=0}^{\infty} \mathbb{I}_{\{u \neq v+j-i\}} \gamma_u \gamma_v \varepsilon_{t-i-u} \varepsilon_{t-j-v} \mathbb{I}_{|\varepsilon_{t-i-u} \varepsilon_{t-j-v}| R \tilde{a}_T},$$

$R \in \{>, \leq\}$. With $C^k := (c_{ij}^k)_{i,j=0}^{k-1}$, it holds that

$$\begin{aligned} \|S_{00}^k - C^k\|_2 &\leq \|(\xi_{ij}^{\leq})_{i,j}\|_2 + \|(\xi_{0,|i-j|}^{\geq})_{i,j}\|_2 + \|(\xi_{0,|i-j|}^{\geq} - \xi_{ij}^{\geq})_{i,j}\|_2 \\ &\leq \|(\xi_{ij}^{\leq})_{i,j}\|_2 + \max_{i=0,\dots,k-1} \sum_{j=0}^{k-1} |\xi_{0,|i-j|}^{\geq}| + \sum_{i,j=0}^{k-1} |\xi_{0,|i-j|}^{\geq} - \xi_{ij}^{\geq}| \end{aligned}$$

since $\|(\xi_{0,|i-j|}^{\geq})_{i,j}\|_2 \leq \max_{i=0,\dots,k-1} \sum_{j=0}^{k-1} |\xi_{0,|i-j|}^{\geq}|$ as $(\xi_{0,|i-j|}^{\geq})_{i,j}$ is symmetric (in general, $\|\cdot\|_2 \leq \|\cdot\|_1^{1/2} \|\cdot\|_\infty^{1/2}$). Let first $\mathbb{E}|\varepsilon_1| = \infty$ (so $\alpha \in (0, 1]$). Since $\|\cdot\|_2 \leq \|\cdot\|$, the inequalities can be continued as

$$\|S_{00}^k - C^k\|_2 \leq (\Xi_1^{\leq} + \Xi_2^{\leq})^{1/2} + 2 \sum_{j=0}^{k-1} |\xi_{0,j}^{\geq}| + \sum_{i,j=0}^{k-1} |\xi_{0,|i-j|}^{\geq} - \xi_{ij}^{\geq}|,$$

where

$$\begin{aligned}\Xi_1^{\leq} &:= \sum_{i,j} \sum_{s,t=k}^{T-1} \sum_{a,b,u,v=0}^{\infty} \mathbb{I}_{A^c} \gamma_a \gamma_b \gamma_u \gamma_v \varepsilon_{s-i-a} \varepsilon_{s-j-b} \varepsilon_{t-i-u} \varepsilon_{t-j-v} \\ &\quad \times \mathbb{I}_{|\varepsilon_{s-i-a} \varepsilon_{s-j-b}| \leq \tilde{a}_T} \mathbb{I}_{|\varepsilon_{t-i-u} \varepsilon_{t-j-v}| \leq \tilde{a}_T}, \\ \Xi_2^{\leq} &:= \sum_{i,j} \sum_{s,t=k}^{T-1} \sum_{a,b,u,v=0}^{\infty} \mathbb{I}_{A^c} \gamma_a \gamma_b \gamma_u \gamma_v \varepsilon_{s-i-a} \varepsilon_{s-j-b} \varepsilon_{t-i-u} \varepsilon_{t-j-v} \\ &\quad \times \mathbb{I}_{|\varepsilon_{s-i-a} \varepsilon_{s-j-b}| \leq \tilde{a}_T} \mathbb{I}_{|\varepsilon_{t-i-u} \varepsilon_{t-j-v}| \leq \tilde{a}_T},\end{aligned}$$

$A := \{\#\{s-i-a, s-j-b, t-i-u, t-j-v\} = 4\}$, $A^c := \{\#\{s-i-a, s-j-b, t-i-u, t-j-v\} = 2 \text{ or } 3\}$. Further,

$$\mathbb{E} |\Xi_1^{\leq}| \leq k^2 T^2 \mathbb{E} (|\varepsilon_1 \varepsilon_2| \mathbb{I}_{|\varepsilon_1 \varepsilon_2| \leq \tilde{a}_T})^2 (\sum_{u=0}^{\infty} |\gamma_u|)^4 = O(k^2 \tilde{a}_T^2)$$

for $\alpha \in (0, 1)$, as $\tilde{a}_T^{-1} T \mathbb{E} (|\varepsilon_1 \varepsilon_2| \mathbb{I}_{|\varepsilon_1 \varepsilon_2| \leq \tilde{a}_T}) \rightarrow \alpha / (1 - \alpha)$ by Karamata's theorem [KT], and $\mathbb{E} |\Xi_1^{\leq}| = O(k^2 l_T^2 \tilde{a}_T^2)$ for $\alpha = 1$, as $\tilde{a}_T^{-1} T \mathbb{E} (|\varepsilon_1 \varepsilon_2| \mathbb{I}_{|\varepsilon_1 \varepsilon_2| \leq \tilde{a}_T})$ is slowly varying in this case. Similarly,

$$\mathbb{E} |\Xi_2^{\leq}| \leq 4k^2 T \mathbb{E} (|\varepsilon_1^2 \varepsilon_2^2| \mathbb{I}_{|\varepsilon_1 \varepsilon_2| \leq \tilde{a}_T}) (\sum_{u=0}^{\infty} |\gamma_u|)^4 = O(k^2 \tilde{a}_T^2)$$

by KT, so $\Xi_1^{\leq} + \Xi_2^{\leq} = O_P(k^2 l_T^2 \tilde{a}_T^2)$. Also, for every $\eta \in (\delta, \alpha)$,

$$\mathbb{E} \left| \sum_{j=0}^{k-1} |\xi_{0,j}^{\gt}| \right|^\eta \leq kT \mathbb{E} (|\varepsilon_1 \varepsilon_2|^\eta \mathbb{I}_{|\varepsilon_1 \varepsilon_2| > \tilde{a}_T}) \left(\sum_{u=0}^{\infty} |\gamma_u|^\eta \right)^2 = O(k \tilde{a}_T^\eta) \quad (\text{A.1.5})$$

by KT with $\mathbb{E} (|\varepsilon_1 \varepsilon_2|^\eta) < \infty$, so $\sum_{j=0}^{k-1} |\xi_{0,j}^{\gt}| = O_P(k^{1/\eta} \tilde{a}_T)$ by Markov's inequality, and by letting $\eta \uparrow \alpha$, $\sum_{j=0}^{k-1} |\xi_{0,j}^{\gt}| = o_P(k^\epsilon a_k \tilde{a}_T)$ for every $\epsilon > 0$. Similarly, since $|\xi_{0,|i-j}^{\gt}| - \xi_{ij}^{\gt}|$ does not exceed

$$\left(\sum_{t=k-i \wedge j}^{k-1} + \sum_{t=T-i \wedge j}^{T-1} \right) \sum_{u,v=0}^{\infty} \mathbb{I}_{\{u \neq v + |j-i|\}} |\gamma_u| |\gamma_v| |\varepsilon_{t-u} \varepsilon_{t-|j-i|-v}| \mathbb{I}_{|\varepsilon_{t-u} \varepsilon_{t-|j-i|-v}| > \tilde{a}_T},$$

with $i \wedge j := \min(i, j)$, it follows that

$$\mathbb{E} \left| \sum_{i,j=0}^{k-1} |\xi_{0,|i-j}^{\gt}| - \xi_{ij}^{\gt}| \right|^\eta \leq (k+1)^3 \mathbb{E} (|\varepsilon_1 \varepsilon_2|^\eta \mathbb{I}_{|\varepsilon_1 \varepsilon_2| > \tilde{a}_T}) \left(\sum_{u=0}^{\infty} |\gamma_u|^\eta \right)^2 \quad (\text{A.1.6})$$

is $O((k^3/T) \tilde{a}_T^\eta) = o(k \tilde{a}_T^\eta)$, so $\sum_{i,j=0}^{k-1} |\xi_{0,|i-j}^{\gt}| - \xi_{ij}^{\gt}| = o_P(k^\epsilon a_k \tilde{a}_T)$ for every $\epsilon > 0$. By combining these results, also $\|S_{00}^k - C^k\|_2 = o_P(k^\epsilon a_k l_T \tilde{a}_T)$.

Instead, for $\mathbb{E} |\varepsilon_1| < \infty$ (so $\alpha \in [1, 2)$), we write $\|(\xi_{ij})_{i,j}^{\leq}\|_2 \leq \sqrt{2} (\Xi_3^{\leq} + \Xi_4^{\leq})^{1/2}$ with

$$\begin{aligned}\Xi_3^{\leq} &:= \sum_{i,j} \left\{ \sum_{t=k}^{T-1} \sum_{u,v=0}^{\infty} \mathbb{I}_{\{u \neq v + j - i\}} \gamma_u \gamma_v (\varepsilon_{t-i-u} \varepsilon_{t-j-v} \mathbb{I}_{|\varepsilon_{t-i-u} \varepsilon_{t-j-v}| \leq \tilde{a}_T} - \mu_T) \right\}^2, \\ \Xi_4^{\leq} &:= \mu_T^2 \sum_{i,j} \left\{ \sum_{t=k}^{T-1} \sum_{u,v=0}^{\infty} \mathbb{I}_{\{u \neq v + j - i\}} \gamma_u \gamma_v \right\}^2\end{aligned}$$

and $\mu_T := \mathbb{E} (\varepsilon_1 \varepsilon_2 \mathbb{I}_{|\varepsilon_1 \varepsilon_2| \leq \tilde{a}_T})$, so

$$\|S_{00}^k - C^k\|_2 \leq \sqrt{2} (\Xi_3^{\leq} + \Xi_4^{\leq})^{1/2} + 2 \sum_{j=0}^{k-1} |\xi_{0,j}^{\gt}| + \sum_{i,j=0}^{k-1} |\xi_{0,|i-j}^{\gt}| - \xi_{ij}^{\gt}|.$$

The terms in the upper bound satisfy: (i) $\Xi_3^{\leq} = O_P(k^2 \tilde{a}_T^2)$, as

$$\mathbb{E} |\Xi_3^{\leq}| \leq 4k^2 T \mathbb{E} (\varepsilon_1 \varepsilon_2 \mathbb{I}_{|\varepsilon_1 \varepsilon_2| \leq \tilde{a}_T} - \mu_T)^2 \left(\sum |\gamma_u| \right)^4 \leq O(k^2 T) \mathbb{E} (|\varepsilon_1 \varepsilon_2|^2 \mathbb{I}_{|\varepsilon_1 \varepsilon_2| \leq \tilde{a}_T})$$

is $O(k^2\tilde{a}_T^2)$ by independence and KT; (ii) $|\Xi_4^\leq| \leq \mu_T^2 k^2 T^2 (\sum |\gamma_u|)^4 = O(k^2\tilde{a}_T^2)$ for $\alpha \in (1, 2)$ since

$$\begin{aligned} |\mu_T| &= |\mathbf{E}(\varepsilon_1 \varepsilon_2 \mathbb{I}_{|\varepsilon_1 \varepsilon_2| \leq \tilde{a}_T})| = |-\mathbf{E}(\varepsilon_1 \varepsilon_2 \mathbb{I}_{|\varepsilon_1 \varepsilon_2| > \tilde{a}_T})| \\ &\leq \mathbf{E}(|\varepsilon_1 \varepsilon_2| \mathbb{I}_{|\varepsilon_1 \varepsilon_2| > \tilde{a}_T}) = O(T^{-1} \tilde{a}_T) \end{aligned} \quad (\text{A.1.7})$$

using $\mathbf{E}(\varepsilon_1 \varepsilon_2) = 0$ and KT, whereas $|\Xi_4^\leq| = O_P(k^2 T^2) = O_P(k^2 l_T^2 a_T^2)$ for $\alpha = 1$ as $\mu_T = O(1)$; (iii) $2 \sum_{j=0}^{k-1} |\xi_{0,j}^\geq| + \sum_{i,j=0}^{k-1} |\xi_{0,|i-j|}^\geq - \xi_{ij}^\geq| = O_P(k\tilde{a}_T)$ for $\alpha \in (1, 2)$ by (A.1.5)-(A.1.6) with $\eta = 1$, and $2 \sum_{j=0}^{k-1} |\xi_{0,j}^\geq| + \sum_{i,j=0}^{k-1} |\xi_{0,|i-j|}^\geq - \xi_{ij}^\geq| = O_P(kT) = O_P(kl_T \tilde{a}_T)$ for $\alpha = 1$ using the same displays. Thus, $\|S_{00}^k - C^k\|_2 = O_P(kl_T \tilde{a}_T)$ in the case $\mathbf{E}|\varepsilon_1| < \infty$, and by the earlier argument, $\|S_{00}^k - C^k\|_2 = O_P(l_T \tilde{a}_T) \max\{k^\epsilon a_k, k\}$ for all $\alpha \in (0, 2)$ and $\epsilon > 0$.

In its turn,

$$c_{ij}^k = r_{|i-j|} \sum_{t=k}^{T-1} \varepsilon_{t-\max(i,j)}^2 + \sum_{v=0}^{\infty} \rho_v^{ij} [\varepsilon_{k-\max(i,j)-v}^2 - \varepsilon_{T-\max(i,j)-1-v}^2], \quad (\text{A.1.8})$$

where $\rho_v^{ij} := \sum_{u=v+1}^{\infty} \gamma_u \gamma_{u+|j-i|}$ has $|\rho_v^{ij}| \leq \sum_{u=v+1}^{\infty} \gamma_u^2 := \tilde{\gamma}_v^2$. For δ of Assumption 1(b) it follows that $\sum_{v=0}^{\infty} |\rho_v^{ij}|^{\delta/2} \leq \sum_{v=0}^{\infty} \sum_{u=v+1}^{\infty} |\gamma_u|^\delta = \sum_{u=1}^{\infty} u |\gamma_u|^\delta < \infty$, so the series in (A.1.8) are a.s. convergent because ε_t^2 has tail index $\alpha/2$. Further, as $r_{|i-j|}^2 \leq r_0^2$,

$$\begin{aligned} \|\Sigma_k \sigma_T^2 - C^k\|_2^2 &\leq \|\Sigma_k \sigma_T^2 - C^k\|^2 \\ &\leq 3 \left(\sum_{t=1}^k \varepsilon_t^2 + \sum_{t=T-k}^T \varepsilon_t^2 \right)^2 \sum_{i,j} r_{ij}^2 + 3 \sum_{i,j} \left(\sum_{v=0}^{\infty} \tilde{\gamma}_v^2 \varepsilon_{T-\max(i,j)-1-v}^2 \right)^2 \\ &\quad + 3 \sum_{i,j} \left(\sum_{v=0}^{\infty} \tilde{\gamma}_v^2 \varepsilon_{k-\max(i,j)-v}^2 \right)^2 \leq 3k^2 [O_P(a_k^4) r_{00}^2 \\ &\quad + \max_{i=1,\dots,k} \left(\sum_{v=0}^{\infty} \tilde{\gamma}_v^2 \varepsilon_{T-i-v}^2 \right)^2 + \max_{i=1,\dots,k} \left(\sum_{v=0}^{\infty} \tilde{\gamma}_v^2 \varepsilon_{k-i-v}^2 \right)^2] = O_P(k^2 a_k^4) \end{aligned} \quad (\text{A.1.9})$$

using that $\max_{i=1,\dots,k} |a_k^{-2} \sum_{v=0}^{\infty} \tilde{\gamma}_v^2 \varepsilon_{T-i-v}^2|$, $\max_{i=1,\dots,k} |a_k^{-2} \sum_{v=0}^{\infty} \tilde{\gamma}_v^2 \varepsilon_{k-i-v}^2|$, $a_k^{-2} \sum_{t=1}^k \varepsilon_t^2$ and $a_k^{-2} \sum_{t=T-k}^T \varepsilon_t^2$ converge weakly to a.s. finite r.v.'s (see Theorem 3.2 of Davis and Resnick (1985a) for the former two, as ε_t^2 are in the $\alpha/2$ -stable domain of attraction with normalisation a_T^2). From the triangle inequality and the condition $k^2/T \rightarrow 0$, we conclude that, for every $\epsilon > 0$,

$$\|S_{00}^k - \Sigma_k \sigma_T^2\|_2 = O_P(l_T \tilde{a}_T) \max\{k^\epsilon a_k, k\}. \quad (\text{A.1.10})$$

Regarding $S_{0\epsilon}^k$ in part (b), first,

$$\left\| \sum_{t=k+1}^T \mathbf{X}_{t-1}^k \varepsilon_t \right\|^2 = \sum_{i=1}^k \left(\sum_{t=k+1}^T \sum_{j=0}^{\infty} \gamma_j \varepsilon_{t-j-i} \varepsilon_t \right)^2.$$

For $\{\varepsilon_t\}$ with $\mathbf{E}|\varepsilon_1| = \infty$ (and hence, $\alpha \leq 1$), we write $\left\| \sum_{t=k+1}^T \mathbf{X}_{t-1}^k \varepsilon_t \right\|^2 \leq 2\{(\Lambda_1^\geq)^2 + \Lambda_1 + \Lambda_2\}$ with

$$\begin{aligned} \Lambda_1^\geq &:= \sum_{i=1}^k \sum_{t=k+1}^T \sum_{j=0}^{\infty} |\gamma_j| |\varepsilon_{t-j-i} \varepsilon_t| \mathbb{I}_{|\varepsilon_{t-j-i} \varepsilon_t| > \tilde{a}_T} \\ \Lambda_1 &:= \sum_{i=1}^k \sum_{s,t=k+1}^T \sum_{h,j=0}^{\infty} \mathbb{I}_B \gamma_h \gamma_j \varepsilon_{s-h-i} \varepsilon_s \varepsilon_{t-j-i} \varepsilon_t \mathbb{I}_{|\varepsilon_{s-h-i} \varepsilon_s| \leq \tilde{a}_T} \mathbb{I}_{|\varepsilon_{t-j-i} \varepsilon_t| \leq \tilde{a}_T}, \\ \Lambda_2 &:= \sum_{i=1}^k \sum_{s,t=k+1}^T \sum_{h,j=0}^{\infty} \mathbb{I}_B \gamma_h \gamma_j \varepsilon_{s-h-i} \varepsilon_s \varepsilon_{t-j-i} \varepsilon_t \mathbb{I}_{|\varepsilon_{s-h-i} \varepsilon_s| \leq \tilde{a}_T} \mathbb{I}_{|\varepsilon_{t-j-i} \varepsilon_t| \leq \tilde{a}_T}, \end{aligned}$$

$B := \{\#\{s, t, s-h-i, t-j-i\} = 4\}$, $B^c := \{\#\{s, t, s-h-i, t-j-i\} = 2 \text{ or } 3\}$. Similarly to the evaluations of $(\Xi^>)^2, \Xi_{1,2}$, we find for $\eta \in (\delta, \alpha)$ that $\mathbb{E}|\Lambda_1^>|^\eta = O(k\tilde{a}_T^\eta)$, $\mathbb{E}|\Lambda_1| = O(kl_T^2\tilde{a}_T^2)$ and $\mathbb{E}|\Lambda_2| = O(k\tilde{a}_T^2)$, so $\Lambda_1^> = o_P(k^\epsilon a_k \tilde{a}_T)$ for every $\epsilon > 0$, $\Lambda_1 = O_P(kl_T^2\tilde{a}_T^2)$ for l_T as in part (a), and $\Lambda_2 = O_P(k\tilde{a}_T^2)$, giving $\|\sum_{t=k+1}^T \mathbf{X}_{t-1}^k \varepsilon_t\| = o_P(k^\epsilon a_k l_T \tilde{a}_T)$ for every $\epsilon > 0$. On the other hand, in the case $\mathbb{E}|\varepsilon_1| < \infty$ (where $\alpha \geq 1$), $\|\sum_{t=k+1}^T \mathbf{X}_{t-1}^k \varepsilon_t\|^2 \leq 3(\Lambda_2^> + \Lambda_3 + \Lambda_4)$ with

$$\Lambda_2^> := \sum_{i=1}^k (\sum_{t=k+1}^T \sum_{j=0}^{\infty} |\gamma_j| |\varepsilon_{t-j-i} \varepsilon_t| \mathbb{I}_{|\varepsilon_{t-j-i} \varepsilon_t| > \tilde{a}_T})^2$$

satisfying by KT $\mathbb{E}|\Lambda_2^>|^{\eta/2} \leq kT \mathbb{E}(|\varepsilon_1 \varepsilon_2|^\eta \mathbb{I}_{|\varepsilon_1 \varepsilon_2| > \tilde{a}_T}) (\sum |\gamma_u|^\eta) = O(k\tilde{a}_T^\eta)$ for $\eta \in [1, \alpha)$, $\alpha > 1$, whereas $\mathbb{E}|\Lambda_2^>|^{1/2} = O(kT) = O(kl_T \tilde{a}_T)$ for $\alpha = 1$, so $\Lambda_2^> = O_P(k^\epsilon a_k^2 l_T^2 \tilde{a}_T^2)$ by Markov's inequality, and

$$\begin{aligned} \Lambda_3 &:= \sum_{i=1}^k \left\{ \sum_{t=k+1}^T \sum_{j=0}^{\infty} \gamma_j (\varepsilon_{t-j-i} \varepsilon_t \mathbb{I}_{|\varepsilon_{t-j-i} \varepsilon_t| \leq \tilde{a}_T} - \mu_T) \right\}^2 = O_P(k\tilde{a}_T^2), \\ \Lambda_4 &:= \mu_T^2 \sum_{i=1}^k (\sum_{t=k+1}^T \sum_{j=0}^{\infty} \gamma_j)^2 = O(kl_T^2 \tilde{a}_T^2) \end{aligned}$$

as $\Xi_{3,4}$ earlier. Thus, $\|\sum_{t=k+1}^T \mathbf{X}_{t-1}^k \varepsilon_t\| = O_P(k^\epsilon a_k l_T \tilde{a}_T)$ for every $\epsilon > 0$ in the case $\mathbb{E}|\varepsilon_1| < \infty$, and by the previous argument, for all $\alpha \in (0, 2)$.

Second,

$$\begin{aligned} \left\| \sum_{t=k+1}^T \mathbf{X}_{t-1}^k \rho_{t,k} \right\| &= \left\{ \sum_{i=1}^k \left(\sum_{j=k+1}^{\infty} \beta_j \sum_{t=k+1}^T X_{t-i} X_{t-j} \right)^2 \right\}^{1/2} \\ &\leq \sqrt{2} \sum_{i=1}^k \sum_{j=k+1}^{\infty} |\beta_j| |c_{ij}^k| + \sqrt{2} \left\{ \sum_{i=1}^k \left(\sum_{j=k+1}^{\infty} \beta_j \xi_{ij} \right)^2 \right\}^{1/2} \end{aligned}$$

where $c_{ij}^k := \sum_{t=k}^{T-1} \sum_{v=0}^{\infty} \varepsilon_{t-j-v}^2 \gamma_v \gamma_{v+j-i}$ is

$$c_{ij}^k = r_{j-i} \sum_{t=k}^{T-1} \varepsilon_{t-j}^2 - \sum_{v=0}^{\infty} \rho_v^{ij} \varepsilon_{T-j-v-1}^2 + \sum_{v=0}^{\infty} \rho_v^{ij} \varepsilon_{k-j-v}^2$$

and $\xi_{ij} := \sum_{t=k}^{T-1} \sum_{u=0}^{\infty} \sum_{v=0}^{\infty} \mathbb{I}_{\{u \neq v+j-i\}} \gamma_u \gamma_v \varepsilon_{t-i-u} \varepsilon_{t-j-v}$; cf. (A.1.8) with $i < j$. We find that (i)

$$\sum_{i=1}^k \sum_{j=k+1}^{\infty} |\beta_j| |r_{j-i}| \sum_{t=k}^{T-1} \varepsilon_{t-j}^2 \leq \left\{ \sum_{j=k+1}^{\infty} |\beta_j| \right\} \left\{ \sum_{t=k}^{T-1} \sum_{j=k+1}^{\infty} \left(\sum_{i=1}^k |r_{j-i}| \varepsilon_{t-j}^2 \right) \right\},$$

where $\sum_{t=k}^{T-1} \sum_{j=k+1}^{\infty} (\sum_{i=1}^k |r_{j-i}|) \varepsilon_{t-j}^2$ is distributed like

$$\begin{aligned} &\sum_{t=0}^{T-k-1} \sum_{j=1}^{\infty} \left(\sum_{i=j}^{j+k-1} |r_i| \right) \varepsilon_{t-j}^2 \leq T \mathbb{E}[\varepsilon_1^2 \mathbb{I}_{|\varepsilon_1| \leq a_T}] \sum_{j=1}^{\infty} \sum_{i=j}^{\infty} |r_i| \\ &+ \sum_{t=0}^{T-1} \sum_{j=1}^{\infty} \left(\sum_{i=j}^{\infty} |r_i| \right) (\varepsilon_{t-j}^2 - \mathbb{E}[\varepsilon_{t-j}^2 \mathbb{I}_{|\varepsilon_{t-j}| \leq a_T}]) = O_P(a_T^2) \end{aligned}$$

since ε_t^2 have tail index $\alpha/2$ and

$$\sum_{j=1}^{\infty} \left(\sum_{i=j}^{\infty} |r_i| \right)^{\delta/2} \leq \sum_{s=0}^{\infty} |\gamma_s|^{\delta/2} \sum_{j=1}^{\infty} j |\gamma_{s+j}|^{\delta/2} \leq \sum_{s=0}^{\infty} |\gamma_s|^{\delta/2} \sum_{s=0}^{\infty} s |\gamma_s|^{\delta/2} < \infty$$

by Assumption 1(b), so Theorem 4.1 of Davis and Resnick (1985a) applies (with their $c_j = \sum_{i=j}^{\infty} |r_i|$) jointly with KT; (ii)

$$\sum_{i=1}^k \sum_{j=k+1}^{\infty} |\beta_j| \sum_{v=0}^{\infty} |\rho_v^{ij}| \varepsilon_{T-j-v-1}^2 \leq \left\{ \sum_{j=k+1}^{\infty} |\beta_j| \right\} \left\{ \sum_{i=1}^k \sum_{j=k+1}^{\infty} \sum_{v=0}^{\infty} |\rho_v^{ij}| \varepsilon_{T-j-v-1}^2 \right\}$$

with

$$\begin{aligned} \mathbb{E} \left(\sum_{i=1}^k \sum_{j=k+1}^{\infty} \sum_{v=0}^{\infty} |\rho_v^{ij}| \varepsilon_{T-j-v-1}^2 \mathbb{I}_{|\varepsilon_{T-j-v-1}| \leq a_T} \right) &\leq \mathbb{E}(\varepsilon_1^2 \mathbb{I}_{|\varepsilon_1| \leq a_T}) \sum_{i=1}^k \sum_{j=k+1}^{\infty} \sum_{v=0}^{\infty} |\rho_v^{ij}| \\ &\leq O(T^{-1} a_T^2) \sum_{i=1}^k \sum_{j=k+1}^{\infty} \sum_{v=0}^{\infty} \sum_{u=v+1}^{\infty} |\gamma_u| |\gamma_{u+i-j}| \leq O(T^{-1} a_T^2) \left(\sum_{u=1}^{\infty} u |\gamma_u| \right)^2 \end{aligned}$$

and similarly, for $\eta \in (\delta, \alpha)$,

$$\mathbb{E} \left(\sum_{i=1}^k \sum_{j=k+1}^{\infty} \sum_{v=0}^{\infty} |\rho_v^{ij}| \varepsilon_{T-j-v-1}^2 \mathbb{I}_{|\varepsilon_{T-j-v-1}| > a_T} \right)^{\eta/2} \leq \mathbb{E}(|\varepsilon_1|^{\eta} \mathbb{I}_{|\varepsilon_1| \leq a_T}) \left(\sum_{u=1}^{\infty} u |\gamma_u|^{\eta/2} \right)^2$$

is $O(T^{-1} a_T^{\eta})$ by KT, so $\sum_{i=1}^k \sum_{j=k+1}^{\infty} \sum_{v=0}^{\infty} |\rho_v^{ij}| \varepsilon_{T-j-v-1}^2 = o_P(a_T^2)$; (iii),

$$\sum_{i=1}^k \sum_{j=k+1}^{\infty} |\beta_j| \sum_{v=0}^{\infty} |\rho_v^{ij}| \varepsilon_{k-j-v}^2 = o_P(a_T^2) \sum_{j=k+1}^{\infty} |\beta_j|$$

likewise. Thus, $\sum_{i=1}^k \sum_{j=k+1}^{\infty} |\beta_j| |c_{ij}^k| = O_P(a_T^2) \sum_{j=k+1}^{\infty} |\beta_j|$ by combining the previous estimates.

Further, we split $\xi_{ij} = \xi_{ij}^{\leq} + \xi_{ij}^{\geq}$ as in the proof of part (a):

$$\xi_{ij}^R := \sum_{t=k}^{T-1} \sum_{u,v=0}^{\infty} \mathbb{I}_{\{u \neq v+j-i\}} \gamma_u \gamma_v \varepsilon_{t-i-u} \varepsilon_{t-j-v} \mathbb{I}_{|\varepsilon_{t-i-u} \varepsilon_{t-j-v}| R \bar{a}_T}, \quad R \in \{\leq, >\},$$

and for $\{\varepsilon_t\}$ with $\mathbb{E}|\varepsilon_1| = \infty$ we find that,

$$\mathbb{E} \left(\sum_{i=1}^k \sum_{j=k+1}^{\infty} |\beta_j| |\xi_{ij}^{\leq}| \right) \leq Tk \mathbb{E}(|\varepsilon_1 \varepsilon_2| \mathbb{I}_{|\varepsilon_1 \varepsilon_2| \leq \bar{a}_T}) \left(\sum_{u=0}^{\infty} |\gamma_u| \right)^2 \sum_{j=k+1}^{\infty} |\beta_j|$$

is $o(a_T^2) \sum_{j=k+1}^{\infty} |\beta_j|$ by KT, and similarly, for $\eta \in (\delta, \alpha)$,

$$\mathbb{E} \left(\sum_{i=1}^k \sum_{j=k+1}^{\infty} |\beta_j| |\xi_{ij}^{\geq}| \right)^{\eta} \leq Tk \mathbb{E}(|\varepsilon_1 \varepsilon_2|^{\eta} \mathbb{I}_{|\varepsilon_1 \varepsilon_2| > \bar{a}_T}) \left(\sum_{u=0}^{\infty} |\gamma_u|^{\eta} \right)^2 \sum_{j=k+1}^{\infty} |\beta_j|^{\eta}$$

is $O(k \bar{a}_T^{\eta}) \sum_{j=k+1}^{\infty} |\beta_j|^{\eta}$, so by using (A.1.1), $\left\{ \sum_{i=1}^k \left(\sum_{j=k+1}^{\infty} \beta_j \xi_{ij} \right)^2 \right\}^{1/2} \leq \sum_{i=1}^k \sum_{j=k+1}^{\infty} |\beta_j| |\xi_{ij}| = o_P(a_T^{1-\zeta}) + O_P(a_T^2) \sum_{j=k+1}^{\infty} |\beta_j|$ for $\zeta > 0$ sufficiently small, and $\| \sum_{t=k+1}^T \mathbf{X}_{t-1}^k \rho_{t,k} \| = o_P(a_T^{1-\zeta}) + O_P(a_T^2) \sum_{j=k+1}^{\infty} |\beta_j|$ in this case. In the case $\mathbb{E}|\varepsilon_1| < \infty$, as in the proof of part (a), we find that, (i),

$$\begin{aligned} \mathbb{E} \left(\sum_{i=1}^k \left(\sum_{j=k+1}^{\infty} \beta_j \xi_{ij}^{\leq} \right)^2 \right) &\leq \left[\sum_{i=1}^k \sum_{j=k+1}^{\infty} |\beta_j| \mathbb{E} \{ (\xi_{ij}^{\leq})^2 \} \right] \left(\sum_{j=k+1}^{\infty} |\beta_j| \right) \quad (\text{A.1.11}) \\ &\leq k \left[4T \mathbb{E}(\varepsilon_1^2 \varepsilon_2^2 \mathbb{I}_{|\varepsilon_1 \varepsilon_2| \leq \bar{a}_T}) + T^2 \mu_T^2 \right] \left(\sum_{u=0}^{\infty} |\gamma_u| \right)^4 \left(\sum_{j=k+1}^{\infty} |\beta_j| \right)^2 \end{aligned}$$

is $O(kl_T^2 \tilde{a}_T^2) (\sum_{j=k+1}^{\infty} |\beta_j|)^2$, the inequalities respectively from Cauchy-Schwartz and by separating products where some ε is squared from those where all ε 's are distinct, and the magnitude order from KT and (A.1.7), and (ii),

$$\mathbb{E} \left(\sum_{i=1}^k \sum_{j=k+1}^{\infty} |\beta_j| |\xi_{ij}^>| \right) \leq kT \mathbb{E}(|\varepsilon_1 \varepsilon_2| \mathbb{I}_{|\varepsilon_1 \varepsilon_2| > \tilde{a}_T}) \left(\sum_{u=0}^{\infty} |\gamma_u| \right)^2 \sum_{j=k+1}^{\infty} |\beta_j|$$

is $O(kl_T \tilde{a}_T) \sum_{j=k+1}^{\infty} |\beta_j|$ by KT. Thus,

$$\left\{ \sum_{i=1}^k \left(\sum_{j=k+1}^{\infty} \beta_j \xi_{ij} \right)^2 \right\}^{1/2} \leq \sqrt{2} \left\{ \sum_{i=1}^k \left(\sum_{j=k+1}^{\infty} \beta_j \xi_{ij}^{\leq} \right)^2 \right\}^{1/2} + \sqrt{2} \sum_{i=1}^k \sum_{j=k+1}^{\infty} |\beta_j| |\xi_{ij}^>|$$

is $O_P(kl_T \tilde{a}_T) \sum_{j=k+1}^{\infty} |\beta_j|$ with $kl_T \tilde{a}_T = o(a_T^2)$ when $k^2/T \rightarrow 0$. Finally, $\|\sum_{t=k+1}^T \mathbf{X}_{t-1}^k \rho_{t,k}\| = O_P(a_T^2) \sum_{j=k+1}^{\infty} |\beta_j|$ when $\mathbb{E}|\varepsilon_1| < \infty$.

The magnitude order of $S_{0\varepsilon}^k$ is obtained by combining the magnitude orders of $\|\sum_{t=k+1}^T \mathbf{X}_{t-1}^k \varepsilon_t\|$ and $\|\sum_{t=k+1}^T \mathbf{X}_{t-1}^k \rho_{t,k}\|$. \square

A.3.2 PROOF OF COROLLARY 1

Using the fact that $\hat{\Gamma}_k^{-1}$ is the lower triangular Toeplitz matrix with first column $(1 : -\hat{\beta}'_{k-1})'$, it can be checked directly that $\hat{\Gamma}_k^{-1} \gamma_k = (I_k - \Gamma_k) \hat{\beta}_k + \gamma_k$, from where

$$\begin{aligned} \hat{\gamma}_k - \gamma_k &= \hat{\Gamma}_k \hat{\beta}_k - \gamma_k = \hat{\Gamma}_k (\hat{\beta}_k - \hat{\Gamma}_k^{-1} \gamma_k) = \hat{\Gamma}_k (\Gamma_k \hat{\beta}_k - \gamma_k) \\ &= \hat{\Gamma}_k (\Gamma_k \hat{\beta}_k - \Gamma_k \beta_k) = \hat{\Gamma}_k \Gamma_k (\hat{\beta}_k - \beta_k). \end{aligned}$$

Hence, $\|\hat{\gamma}_k - \gamma_k\|_1 \leq \|\hat{\Gamma}_k\|_1 \|\Gamma_k\|_1 \|\hat{\beta}_k - \beta_k\|_1$, where $\|\cdot\|_1$ equals the maximum absolute column sum. As $\|\Gamma_k\|_1 \leq \|\gamma\|_1 := \sum_{i=0}^{\infty} |\gamma_i| < \infty$, and thus,

$$\|\hat{\Gamma}_k\|_1 \leq \|\Gamma_k\|_1 + \|\hat{\Gamma}_k - \Gamma_k\|_1 \leq \|\gamma\|_1 + \|\hat{\gamma}_k - \gamma_k\|_1,$$

it holds further that $\|\hat{\gamma}_k - \gamma_k\|_1 \leq (\|\gamma\|_1 + \|\hat{\gamma}_k - \gamma_k\|_1) \|\gamma\|_1 \|\hat{\beta}_k - \beta_k\|_1$ and, for small $\|\hat{\beta}_k - \beta_k\|_1$, $\|\hat{\gamma}_k - \gamma_k\|_1 \leq \|\hat{\beta}_k - \beta_k\|_1 \|\gamma\|_1^2 / (1 - \|\gamma\|_1 \|\hat{\beta}_k - \beta_k\|_1)$. Hence, $\|\hat{\gamma}_k - \gamma_k\|_1 = O_P(\|\hat{\beta}_k - \beta_k\|_1) = O_P(k^{1/2} \|\hat{\beta}_k - \beta_k\|) = o_P(1)$ by (10) with $k^2/T \rightarrow 0$ and $k^{1/2} \sum_{j=k+1}^{\infty} |\beta_j| \leq \sum_{j=k+1}^{\infty} j |\beta_j| = o(1)$.

Similarly, $\|\hat{\gamma}_k - \gamma_k\| \leq \|\hat{\Gamma}_k\|_2 \|\Gamma_k\|_2 \|\hat{\beta}_k - \beta_k\|$, with

$$\begin{aligned} \|\hat{\Gamma}_k\|_2 &\leq \|\Gamma_k\|_2 + \|\hat{\Gamma}_k - \Gamma_k\|_2 \leq \|\Gamma_k\|_2 + \|\hat{\Gamma}_k - \Gamma_k\|_1^{1/2} \|\hat{\Gamma}_k - \Gamma_k\|_{\infty}^{1/2} \\ &\leq \|\Gamma_k\|_2 + \|\hat{\gamma}_k - \gamma_k\|_1, \end{aligned}$$

so $\|\hat{\gamma}_k - \gamma_k\| \leq (\|\Gamma_k\|_2 + \|\hat{\gamma}_k - \gamma_k\|_1) \|\Gamma_k\|_2 \|\hat{\beta}_k - \beta_k\|$. Since $\|\hat{\gamma}_k - \gamma_k\|_1 = o_P(1)$ and $\|\Gamma_k\|_2 \leq \|\Gamma_k\|_1^{1/2} \|\Gamma_k\|_{\infty}^{1/2} \leq \|\gamma\|_1 < \infty$, it follows that $\|\hat{\gamma}_k - \gamma_k\| = O_P(\|\hat{\beta}_k - \beta_k\|) = o_P(1)$. \square

A.3.3 PROOF OF COROLLARY 2

It holds that $|\hat{C}_T(\lambda) - C(\lambda)| \leq R_T(\lambda) + I_T(\lambda)$ with

$$\begin{aligned} R_T(\lambda) &:= \left| 1 + \sum_{j=1}^k \hat{\gamma}_j \cos(\lambda j) \right|^2 - \left| 1 + \sum_{j=1}^{\infty} \gamma_j \cos(\lambda j) \right|^2 \\ &\leq \left(2 + \sum_{j=1}^{\infty} |\gamma_j| + \sum_{j=1}^k |\hat{\gamma}_j| \right) \left(\sum_{j=1}^k |\hat{\gamma}_j - \gamma_j| + \sum_{j=k+1}^{\infty} |\gamma_j| \right) \end{aligned}$$

$$\leq \left(2 + 2 \sum_{j=1}^{\infty} |\gamma_j| + \|\hat{\gamma}_k - \gamma_k\|_1\right) \left(\|\hat{\gamma}_k - \gamma_k\|_1 + \sum_{j=k+1}^{\infty} |\gamma_j|\right) = o_P(1)$$

since $\|\hat{\gamma}_k - \gamma_k\|_1 = o_P(1)$ by the proof of Corollary 1 and $\sum_{j=1}^{\infty} |\gamma_j| < \infty$. Similarly, $I_T(\lambda) := \left| \sum_{j=1}^{\infty} \gamma_j \sin(\lambda j) \right|^2 - \left| \sum_{j=1}^k \hat{\gamma}_j \sin(\lambda j) \right|^2 = o_P(1)$ using the same upper bounds. As these bounds are independent of λ , convergence is uniform in λ . \square

A.4 PROOFS FROM SECTION 7.3.1

Similarly to Lemma 8.3 of Kreiss (1997), the following bounds can be established for $\hat{\gamma}_j$.

LEMMA A.2 *There exist constants $b_{jk} \geq 0$ and C such that, for large k and uniformly in $j \in \mathbb{N}$, it holds that*

$$|\hat{\gamma}_j - \gamma_j| \leq \left(1 + \frac{1}{k}\right)^{-j} O_P(\|\hat{\beta}_k - \beta_k\|_1 + \sum_{j=k+1}^{\infty} |\beta_j|) + b_{jk} \quad (\text{A.1.12})$$

and $\sum_{j=0}^{\infty} b_{jk} \leq C \sum_{j=k+1}^{\infty} |\beta_j|$.

A.4.1 PROOF OF LEMMA 3

PREPARATION From $\hat{\varepsilon}_t - \varepsilon_t = (\beta_k - \hat{\beta}_k)' \mathbf{X}_{t-1}^k + \rho_{t,k}$ it follows that

$$\sum_{t=k+1}^T (\hat{\varepsilon}_t - \varepsilon_t) = \sum_{t=k+1}^T (\mathbf{X}_{t-1}^k)' (\beta_k - \hat{\beta}_k) + \sum_{t=k+1}^T \rho_{t,k}, \quad (\text{A.1.13})$$

where, (i), $\sum_{t=k+1}^T \mathbf{X}_{t-1}^k = O_P(k^{1/2} a_T)$ is implied by the Beveridge-Nelson decomposition of X_t ($X_t = \gamma(1) \varepsilon_t - \Delta Z_t$, $Z_t := \sum_{j=0}^{\infty} \varepsilon_{t-j} \sum_{i=j+1}^{\infty} \gamma_i$), which yields

$$\begin{aligned} \left\| \sum_{t=k+1}^T \mathbf{X}_{t-1}^k \right\| &\leq k^{1/2} |\gamma(1)| \left\| \sum_{t=k}^{T-1} \varepsilon_t \right\| + k \max_{t \in \{0, \dots, k-1\} \cup \{T-k, \dots, T-1\}} (|\varepsilon_t| + |Z_t|) \\ &= O_P(k^{1/2} a_T l_T + k a_k) = O_P(k^{1/2} a_T l_T) \end{aligned}$$

as $a_T^{-1} \sum_{t=k}^{T-1} \varepsilon_t - a_T^{-1} T \mathbb{E}(\varepsilon_1 \mathbb{I}_{|\varepsilon_1| \leq a_T}) = O_P(1)$, $a_T^{-1} T \mathbb{E}(\varepsilon_1 \mathbb{I}_{|\varepsilon_1| \leq a_T}) = l_T$, and (ii), $\sum_{t=k+1}^T \rho_{t,k} = o_P(l_T)$ by Markov's inequality. Indeed, for $\mathbb{E}|\varepsilon_1| < \infty$,

$$\begin{aligned} \left(\sum_{t=k+1}^T \rho_{t,k} \right)^2 &\leq 2 \left(\sum_{t=k+1}^T \sum_{i=k+1}^{\infty} \beta_i \sum_{j=0}^{\infty} \gamma_j \varepsilon_{t-i-j} \mathbb{I}_{|\varepsilon_{t-i-j}| \leq a_T} \right)^2 \\ &\quad + 2 \left(\sum_{t=k+1}^T \sum_{i=k+1}^{\infty} \beta_i \sum_{j=0}^{\infty} \gamma_j \varepsilon_{t-i-j} \mathbb{I}_{|\varepsilon_{t-i-j}| > a_T} \right)^2 := 2R_k^{\leq} + 2R_k^{>} \end{aligned}$$

with

$$\begin{aligned} \mathbb{E} R_k^{\leq} &\leq \mathbb{E}(\varepsilon_1^2 \mathbb{I}_{|\varepsilon_1| \leq a_T}) \sum_{t=k+1}^T \sum_{i,m=k+1}^{\infty} |\beta_i| |\beta_m| \sum_{j,n=0}^{\infty} |\gamma_j| |\gamma_n| \\ &\quad + \{\mathbb{E}(\varepsilon_1 \mathbb{I}_{|\varepsilon_1| \leq a_T})\}^2 \sum_{t,s=k+1}^T \sum_{i,m=k+1}^{\infty} |\beta_i| |\beta_m| \sum_{j,n=0}^{\infty} |\gamma_j| |\gamma_n| \\ &= O(1) \|\gamma\|_1^2 (a_T \sum_{i=k+1}^{\infty} |\beta_i|)^2 = o(1) \end{aligned}$$

by using $\mathbf{E}(\varepsilon_1 \mathbb{I}_{|\varepsilon_1| \leq a_T}) = -\mathbf{E}(\varepsilon_1 \mathbb{I}_{|\varepsilon_1| > a_T})$ and KT ($\|\boldsymbol{\gamma}\|_1 := \sum_{i=0}^{\infty} |\gamma_i|$), and

$$\mathbf{E}(R_k^>)^{1/2} \leq \mathbf{E}(|\varepsilon_1| \mathbb{I}_{|\varepsilon_1| > a_T}) T \sum_{i=k+1}^{\infty} |\beta_i| \sum_{j=0}^{\infty} |\gamma_j| = O(l_T)(a_T \sum_{i=k+1}^{\infty} |\beta_i|) = o(l_T),$$

so $\sum_{t=k+1}^T \rho_{t,k} = o_P(l_T)$ in this case, whereas for $\mathbf{E}|\varepsilon_1| = \infty$ it holds that

$$\begin{aligned} \sum_{t=k+1}^T |\rho_{t,k}| &\leq \sum_{t=k+1}^T \sum_{i=k+1}^{\infty} |\beta_i| |X_{t-i}| \mathbb{I}_{|X_{t-i}| \leq a_T} + \sum_{t=k+1}^T \sum_{i=k+1}^{\infty} |\beta_i| |X_{t-i}| \mathbb{I}_{|X_{t-i}| > a_T} \\ &=: C_k^{\leq} + C_k^{>} \end{aligned}$$

with

$$\begin{aligned} \mathbf{E} C_k^{\leq} &\leq T \mathbf{E}(|X_1| \mathbb{I}_{|X_1| \leq a_T}) \sum_{i=k+1}^{\infty} |\beta_i| = O(l_T)(a_T \sum_{i=k+1}^{\infty} |\beta_i|) = o(l_T), \\ \mathbf{E}(C_k^{>})^\eta &\leq \mathbf{E}\left(\sum_{i=k+1}^{2T-k-1} |X_{T-i}| \mathbb{I}_{|X_{T-i}| > a_T} \sum_{j=k+1}^{\infty} |\beta_j| + \sum_{i=T-k}^{\infty} |X_{-i}| \mathbb{I}_{|X_{-i}| > a_T} \sum_{j=k+1+i}^{T+i} |\beta_j|^\eta\right)^\eta \\ &\leq T \mathbf{E}(|X_1|^\eta \mathbb{I}_{|X_1| > a_T}) \left\{ 2 \left(\sum_{j=k+1}^{\infty} |\beta_j| \right)^\eta + T^{-1} \sum_{i=T-k}^{\infty} \sum_{j=k+1+i}^{T+i} |\beta_j|^\eta \right\} \\ &\leq O(a_T^\eta) \left\{ 2 \left(\sum_{j=k+1}^{\infty} |\beta_j| \right)^\eta + \sum_{j=T+1}^{\infty} |\beta_j|^\eta \right\} \end{aligned}$$

by KT for $\eta \in [\delta, \alpha)$, $\alpha \leq 1$, so from $a_T \sum_{j=k+1}^{\infty} |\beta_j| \rightarrow 0$ and $\sum_{j=T+1}^{\infty} |\beta_j|^\eta = O(T^{1-2\eta/\delta})$ (under $\sum_{j=1}^{\infty} j^{2/\delta} |\beta_j| < \infty$), it follows that $C_k^{>} = o_P(1) + O_P(a_T T^{1/\eta-2/\delta}) = o_P(1)$ as $\eta \in [\delta, \alpha)$ can be chosen such that $1/\alpha + 1/\eta < 2/\delta$; eventually $\sum_{t=k+1}^T |\rho_{t,k}| = o_P(l_T)$ for $\mathbf{E}|\varepsilon_1| = \infty$. Returning to (A.1.13) and using (10), it follows that for all $\varepsilon > 0$,

$$\sum_{t=k+1}^T (\hat{\varepsilon}_t - \varepsilon_t) = O_P(k^{1/2} a_k a_T^\varepsilon + l_T) = O_P(k^{1/2} a_k a_T^\varepsilon). \quad (\text{A.1.14})$$

As $(\hat{\varepsilon}_t - \varepsilon_{t,k})^2 = \{(\hat{\boldsymbol{\beta}}_k - \boldsymbol{\beta}_k)' \mathbf{X}_{t-1}^k\}^2$ and π is a.s. bijective, we find

$$\begin{aligned} \sum_{t=k+1}^T (\hat{\varepsilon}_t - \varepsilon_{t,k})^2 &= (\hat{\boldsymbol{\beta}}_k - \boldsymbol{\beta}_k)' S_{00}^k (\hat{\boldsymbol{\beta}}_k - \boldsymbol{\beta}_k) \leq \|\hat{\boldsymbol{\beta}}_k - \boldsymbol{\beta}_k\|^2 \|S_{00}^k\|_2 \\ &\leq \|\hat{\boldsymbol{\beta}}_k - \boldsymbol{\beta}_k\|^2 (\sigma_T^2 \|\Sigma_k\|_2 + o_P(a_T^2)) = O_P(a_T^2 \|\hat{\boldsymbol{\beta}}_k - \boldsymbol{\beta}_k\|^2) \end{aligned}$$

by Lemma 2(a), and since $\sigma_T^2 = O_P(a_T^2)$ and $\|\Sigma_k\|_2 = O(1)$. Next, from $(\hat{\varepsilon}_t - \varepsilon_t)^2 \leq 2(\hat{\varepsilon}_t - \varepsilon_{t,k})^2 + 2\rho_{t,k}^2$ and the a.s. bijectivity of π , it follows that P^π -a.s. (i.e., conditional on the data and $\{w_t\}_{t=k+1}^T$, with randomness stemming from π alone),

$$\begin{aligned} \sum_{t=k+1}^T (\hat{\varepsilon}_{\pi(t)} - \varepsilon_{\pi(t)})^2 &= \sum_{t=k+1}^T (\hat{\varepsilon}_t - \varepsilon_t)^2 =: \|\hat{\boldsymbol{\varepsilon}}_T - \boldsymbol{\varepsilon}_T\|^2 \\ &\leq 2 \left\{ \sum_{t=k+1}^T (\hat{\varepsilon}_t - \varepsilon_{t,k})^2 + S_{\rho\rho}^k \right\} = O_P(a_T^2 \|\hat{\boldsymbol{\beta}}_k - \boldsymbol{\beta}_k\|^2) + 2S_{\rho\rho}^k, \end{aligned} \quad (\text{A.1.15})$$

where $S_{\rho\rho}^k := \sum_{t=k+1}^T \rho_{t,k}^2 = o_P(l_T)$ by Markov's inequality. In fact, for $\mathbb{E}|\varepsilon_1| < \infty$ it holds that

$$\begin{aligned} S_{\rho\rho}^k &\leq 2 \sum_{t=k+1}^T \left(\sum_{i=k+1}^{\infty} \beta_i \sum_{j=0}^{\infty} \gamma_j \varepsilon_{t-i-j} \mathbb{I}_{|\varepsilon_{t-i-j}| \leq a_T} \right)^2 \\ &\quad + 2 \sum_{t=k+1}^T \left(\sum_{i=k+1}^{\infty} \beta_i \sum_{j=0}^{\infty} \gamma_j \varepsilon_{t-i-j} \mathbb{I}_{|\varepsilon_{t-i-j}| > a_T} \right)^2 =: 2S_{\rho\rho}^{\leq} + 2S_{\rho\rho}^{>} \end{aligned}$$

with (i)

$$\begin{aligned} \mathbb{E} S_{\rho\rho}^{\leq} &= \sum_{t=k+1}^T \mathbb{E} \left(\sum_{i=k+1}^{\infty} \beta_i \sum_{j=0}^{\infty} \gamma_j \varepsilon_{t-i-j} \mathbb{I}_{|\varepsilon_{t-i-j}| \leq a_T} \right)^2 \\ &= \mathbb{E}(\varepsilon_1^2 \mathbb{I}_{|\varepsilon_1| \leq a_T}) \sum_{t=k+1}^T \sum_{i=k+1}^{\infty} \left(\sum_{j=k+1}^i \beta_j \gamma_{i-j} \right)^2 \\ &\quad + \{\mathbb{E}(\varepsilon_1 \mathbb{I}_{|\varepsilon_1| \leq a_T})\}^2 \sum_{t=k+1}^T \sum_{i,m=k+1}^{\infty} \sum_{j,n=0}^{\infty} \mathbb{I}_{\{i+j \neq m+n\}} \beta_j \beta_m \gamma_j \gamma_n \\ &\leq O(a_T^2) \left(\sum_{i=k+1}^{\infty} \sum_{j=k+1}^i |\beta_j| |\gamma_{i-j}| \right)^2 + O(T^{-1} l_T a_T^2) \left(\sum_{j=k+1}^{\infty} |\beta_j|^2 \right) \|\boldsymbol{\gamma}\|_1^2 \\ &\leq O(1) (a_T^2 \sum_{j=k+1}^{\infty} |\beta_j|^2) \|\boldsymbol{\gamma}\|_1^2 = o(1) \end{aligned}$$

by using $\mathbb{E}(\varepsilon_1 \mathbb{I}_{|\varepsilon_1| \leq a_T}) = -\mathbb{E}(\varepsilon_1 \mathbb{I}_{|\varepsilon_1| > a_T})$ and KT, and (ii),

$$\mathbb{E}(S_{\rho\rho}^{>})^{\frac{1}{2}} \leq \mathbb{E}(|\varepsilon_1| \mathbb{I}_{|\varepsilon_1| > a_T}) T \sum_{i=k+1}^{\infty} |\beta_i| \sum_{j=0}^{\infty} |\gamma_j| = O(l_T) (a_T \sum_{i=k+1}^{\infty} |\beta_i|) = o(l_T),$$

whereas for $\mathbb{E}|\varepsilon_1| = \infty$ it holds that $(S_{\rho\rho}^k)^{1/2} \leq \sum_{t=k+1}^T |\rho_{t,k}| = o_P(l_T)$ by the earlier argument for (A.1.13), so $S_{\rho\rho}^k = o_P(l_T)$ independently of $\mathbb{E}|\varepsilon_1|$ (as the square of slowly varying is slowly varying). Thus, continuing (A.1.15),

$$\|\hat{\boldsymbol{\varepsilon}}_T - \boldsymbol{\varepsilon}_T\|^2 = O_P(a_T^2 \|\hat{\boldsymbol{\beta}}_k - \boldsymbol{\beta}_k\|^2) + o_P(l_T) = o_P(a_T^2). \quad (\text{A.1.16})$$

Further, as $\hat{\varepsilon}_t^2 \leq 2\varepsilon_t^2 + 2(\hat{\varepsilon}_t - \varepsilon_t)^2$, it holds P^π -a.s. that

$$\sum_{t=k+1}^T \hat{\varepsilon}_\pi(t)^2 = \sum_{t=k+1}^T \hat{\varepsilon}_t^2 =: \hat{\sigma}_{T,k}^2 \leq 2\sigma_T^2 + 2\|\hat{\boldsymbol{\varepsilon}}_T - \boldsymbol{\varepsilon}_T\|^2 = O_P(a_T^2).$$

PROOF OF PART (A) After this preparation, we turn to

$$\begin{aligned} S_{00}^{*k} - S_{00}^{\dagger k} &= \sum_{t=k+2}^T \left\{ \sum_{j=0}^{t-k-2} \hat{\gamma}_{j:k} \varepsilon_{t-j-1}^* \sum_{j=0}^{t-k-2} \hat{\gamma}'_{j:k} \varepsilon_{t-j-1}^* \right. \\ &\quad \left. - \sum_{j=0}^{t-k-2} \gamma_{j:k} \varepsilon_{t-j-1}^\dagger \sum_{j=0}^{t-k-2} \gamma'_{j:k} \varepsilon_{t-j-1}^\dagger \right\} \\ &= \sum_{t=k+2}^T \sum_{j,i=0}^{t-k-2} w_{t-j-1} w_{t-i-1} \{ \hat{\gamma}_{j:k} \hat{\gamma}'_{i:k} \hat{\varepsilon}_\pi(t-j-1) \hat{\varepsilon}_\pi(t-i-1) \\ &\quad - \gamma_{j:k} \gamma'_{i:k} \varepsilon_{\pi(t-j-1)} \varepsilon_{\pi(t-i-1)} \}. \end{aligned}$$

Let $\mathbf{G}_{ji:k} := \text{vec}(\gamma_{j:k}\gamma'_{i:k})$ and $\hat{\mathbf{G}}_{ji:k} := \text{vec}(\hat{\gamma}_{j:k}\hat{\gamma}'_{i:k})$, such that

$$\begin{aligned} \Delta_{00} := \text{vec}(S_{00}^{*k} - S_{00}^{\dagger k}) &= \sum_{t=k+2}^T \sum_{j,i=0}^{t-k-2} w_{t-j-1}w_{t-i-1}(\hat{\mathbf{G}}_{ji:k}\hat{\varepsilon}_{\pi(t-j-1)}\hat{\varepsilon}_{\pi(t-i-1)} \\ &\quad - \mathbf{G}_{ji:k}\varepsilon_{\pi(t-j-1)}\varepsilon_{\pi(t-i-1)}). \end{aligned}$$

We split Δ_{00} into $\Delta_{00} = \Delta_{00}^{(1)} + \Delta_{00}^{(2)} + \Delta_{00}^{(3)}$ with $\Delta_{00}^{(1)} := \sum_{t=k+1}^{T-1} \varepsilon_{\pi(t)}^2 c_{t,t}$,

$$\begin{aligned} \Delta_{00}^{(2)} &:= \sum_{s,t=k+1}^{T-1} \mathbb{I}_{s \neq t} w_s w_t \varepsilon_{\pi(s)} \varepsilon_{\pi(t)} c_{s,t} \\ \Delta_{00}^{(3)} &:= \sum_{t=k+1}^{T-1} \sum_{j,i=0}^{t-k-2} \hat{\mathbf{G}}_{ji:k} w_{t-j} w_{t-i} (\hat{\varepsilon}_{\pi(t-j)} \hat{\varepsilon}_{\pi(t-i)} - \varepsilon_{\pi(t-j)} \varepsilon_{\pi(t-i)}) \\ &= \sum_{s,t=k+1}^{T-1} w_s w_t (\hat{\varepsilon}_{\pi(s)} \hat{\varepsilon}_{\pi(t)} - \varepsilon_{\pi(s)} \varepsilon_{\pi(t)}) \hat{d}_{s,t}, \end{aligned}$$

where

$$c_{s,t} := \sum_{i=\max\{0,s-t\}}^{T-t-1} (\hat{\mathbf{G}}_{t-s+i,i:k} - \mathbf{G}_{t-s+i,i:k}), \quad \hat{d}_{s,t} := \sum_{i=\max\{0,s-t\}}^{T-t-1} \hat{\mathbf{G}}_{t-s+i,i:k}.$$

For an r.p. π , with \mathbf{E}^\dagger denoting expectation under P^\dagger , it holds that, first, $\mathbf{E}^\dagger \|\Delta_{00}^{(1)}\| \leq \sigma_T^2 \max_{t=k+1, \dots, T} \|c_{t,t}\|$, where $c_{t,t}$ remain to be evaluated.

Second, regarding $\Delta_{00}^{(2)}$, for Rademacher w_t it holds that

$$\begin{aligned} \mathbf{E}^\dagger \|\Delta_{00}^{(2)}\|^2 &= \sum_{s,t=k+1}^{T-1} \mathbb{I}_{s \neq t} \mathbf{E}^\dagger (\varepsilon_{\pi(s)}^2 \varepsilon_{\pi(t)}^2) \{c'_{s,t} c_{s,t} + c'_{s,t} c_{t,s}\} \\ &= \mathbf{E}^\dagger (\varepsilon_{\pi(k+1)}^2 \varepsilon_{\pi(k+2)}^2) \sum_{s,t=k+1}^{T-1} \mathbb{I}_{s \neq t} \{c'_{s,t} c_{s,t} + c'_{s,t} c_{t,s}\} \\ &= O_P(T^{-2} a_T^4) \sum_{s,t=k+1}^{T-1} |c'_{s,t} c_{s,t} + c'_{s,t} c_{t,s}| \end{aligned} \tag{A.1.17}$$

because

$$\begin{aligned} \mathbf{E}^\dagger (\varepsilon_{\pi(k+1)}^2 \varepsilon_{\pi(k+2)}^2) &= \sum_{u,v=k+1}^T \mathbb{I}_{u \neq v} P\{\pi(k+1) = u, \pi(k+2) = v\} \varepsilon_u^2 \varepsilon_v^2 \\ &= O(T^{-2}) \{\sigma_T^4 - \sum_{t=k+1}^T \varepsilon_t^4\} = O_P(T^{-2} a_T^4), \end{aligned} \tag{A.1.18}$$

whereas for $w_t = 1$ a.s. (all t),

$$\mathbf{E}^\dagger \|\Delta_{00}^{(2)}\|^2 = \mathbf{E}^\dagger (\varepsilon_{\pi(k+1)}^2 \varepsilon_{\pi(k+2)}^2) \sum_{s,t=k+1}^{T-1} \mathbb{I}_{s \neq t} \{c'_{s,t} c_{s,t} + c'_{s,t} c_{t,s}\}$$

$$\begin{aligned}
& + \mathbf{E}^\dagger(\varepsilon_{\pi(k+1)}^2 \varepsilon_{\pi(k+2)} \varepsilon_{\pi(T)}) \\
& \times \sum_{s,t,v=k+1}^{T-1} \mathbb{I}_{\#\{s,t,v\}=3} \{c'_{s,t} c_{s,v} + c'_{s,t} c_{v,s} + c'_{t,s} c_{s,v} + c'_{t,s} c_{v,s}\} \\
& + \mathbf{E}^\dagger(\varepsilon_{\pi(k+1)} \varepsilon_{\pi(k+2)} \varepsilon_{\pi(T-1)} \varepsilon_{\pi(T)}) \sum_{s,t,u,v=k+1}^{T-1} \mathbb{I}_{\#\{s,t,u,v\}=4} c'_{s,t} c_{u,v},
\end{aligned}$$

where $\mathbf{E}^\dagger(\varepsilon_{\pi(k+1)}^2 \varepsilon_{\pi(k+2)}^2) = O_P(T^{-2} a_T^4)$ as before,

$$\begin{aligned}
& \mathbf{E}^\dagger(\varepsilon_{\pi(k+1)}^2 \varepsilon_{\pi(k+2)} \varepsilon_{\pi(T)}) \\
& = O(T^{-3}) \{ \sigma_T^2 [(\sum_{t=k+1}^T \varepsilon_t)^2 - \sigma_T^2] - 2[(\sum_{t=k+1}^T \varepsilon_t^3)(\sum_{t=k+1}^T \varepsilon_t) - \sum_{t=k+1}^T \varepsilon_t^4] \}
\end{aligned} \tag{A.1.19}$$

is $O_P(T^{-3} a_T^4 l_T)$ as powers of slowly varying functions vary slowly, and

$$\begin{aligned}
& \mathbf{E}^\dagger(\varepsilon_{\pi(k+1)} \varepsilon_{\pi(k+2)} \varepsilon_{\pi(T-1)} \varepsilon_{\pi(T)}) \\
& \leq O(T^{-4}) \{ (\sum_{t=k+1}^T \varepsilon_t)^4 + \sum_{t=k+1}^T \varepsilon_t^4 + 4\sigma_T^4 + 8(\sum_{t=k+1}^T \varepsilon_t^3)(\sum_{t=k+1}^T \varepsilon_t) \}
\end{aligned} \tag{A.1.20}$$

is $O_P(T^{-4} a_T^4 l_T)$ because $\sum_{t=k+1}^T \varepsilon_t = O_P(a_T l_T)$ and $\sum_{t=k+1}^T \varepsilon_t^i = O_P(a_T^i)$ ($i = 2, \dots, 4$), so

$$\begin{aligned}
& \mathbf{E}^\dagger \|\Delta_{00}^{(2)}\|^2 = O_P(T^{-2} a_T^4) \sum_{s,t=k+1}^{T-1} \mathbb{I}_{s \neq t} |c'_{s,t} c_{s,t} + c'_{s,t} c_{t,s}| \\
& + O_P(T^{-3} a_T^4 l_T) \sum_{s,t,v=k+1}^{T-1} \mathbb{I}_{\#\{s,t,v\}=3} |c'_{s,t} c_{s,v} + c'_{s,t} c_{v,s} + c'_{t,s} c_{s,v} + c'_{t,s} c_{v,s}| \\
& + O_P(T^{-4} a_T^4 l_T) \sum_{s,t,u,v=k+1}^{T-1} \mathbb{I}_{\#\{s,t,u,v\}=4} |c'_{s,t} c_{u,v}|,
\end{aligned} \tag{A.1.21}$$

and $c_{s,t}$ remain to be evaluated.

Third, regarding $\Delta_{00}^{(3)}$, for Rademacher w_t it holds that

$$\begin{aligned}
& \mathbf{E}^\dagger \|\Delta_{00}^{(3)}\|^2 = \sum_{s,t=k+1}^{T-1} \mathbf{E}^\dagger (\hat{\varepsilon}_{\pi(s)} \hat{\varepsilon}_{\pi(t)} - \varepsilon_{\pi(s)} \varepsilon_{\pi(t)})^2 \{ \hat{d}'_{s,t} \hat{d}_{s,t} + \mathbb{I}_{s \neq t} \hat{d}'_{s,t} \hat{d}_{t,s} \} \\
& \leq \mathbf{E}^\dagger (\hat{\varepsilon}_{\pi(k+1)}^2 - \varepsilon_{\pi(k+1)}^2)^2 \sum_{s=k+1}^{T-1} \|\hat{d}_{s,s}\|^2 \\
& + \mathbf{E}^\dagger (\hat{\varepsilon}_{\pi(k+1)} \hat{\varepsilon}_{\pi(k+2)} - \varepsilon_{\pi(k+1)} \varepsilon_{\pi(k+2)})^2 \sum_{s,t=k+1}^{T-1} \mathbb{I}_{s \neq t} |\hat{d}'_{s,t} \hat{d}_{s,t} + \hat{d}'_{s,t} \hat{d}_{t,s}|,
\end{aligned}$$

where $\mathbf{E}^\dagger (\hat{\varepsilon}_{\pi(k+1)}^2 - \varepsilon_{\pi(k+1)}^2)^2$ equals

$$\begin{aligned}
O(T^{-1}) \sum_{s=k+1}^T (\hat{\varepsilon}_s^2 - \varepsilon_s^2)^2 & \leq O(T^{-1}) \|\hat{\varepsilon}_T - \varepsilon_T\|^2 (\sigma_T^2 + \|\hat{\varepsilon}_T - \varepsilon_T\|^2) \\
& = O_P(T^{-1} a_T^4 \|\hat{\beta}_k - \beta_k\|^2) + o_P(T^{-1} l_T a_T^2)
\end{aligned}$$

and is $O_P(T^{-1}a_k^2a_T^{2+\epsilon})$ for all $\epsilon > 0$, using (A.1.16) and (10), and also

$$\begin{aligned} & \mathbb{E}^\dagger(\hat{\varepsilon}_{\pi(k+1)}\hat{\varepsilon}_{\pi(k+2)} - \varepsilon_{\pi(k+1)}\varepsilon_{\pi(k+2)})^2 \\ &= O(T^{-2}) \sum_{s,t=k+1}^T \mathbb{I}_{s \neq t}(\hat{\varepsilon}_s\hat{\varepsilon}_t - \varepsilon_s\varepsilon_t)^2 \leq O(T^{-2})(\hat{\sigma}_{T_k}^2 + \sigma_T^2) \|\hat{\varepsilon}_T - \varepsilon_T\|^2 \\ &= O_P(T^{-2}a_T^4\|\hat{\beta}_k - \beta_k\|^2) + o_P(T^{-2}l_Ta_T^2) \end{aligned} \quad (\text{A.1.22})$$

is $O_P(T^{-2}a_k^2a_T^{2+\epsilon})$ for all $\epsilon > 0$, so

$$\begin{aligned} \mathbb{E}^\dagger \|\Delta_{00}^{(3)}\|^2 &= O_P(T^{-1}a_k^2a_T^{2+\epsilon}) \sum_{s=k+1}^{T-1} \|\hat{d}_{s,s}\|^2 \\ &+ O_P(T^{-2}a_k^2a_T^{2+\epsilon}) \sum_{s,t=k+1}^{T-1} \mathbb{I}_{s \neq t} |\hat{d}'_{s,t}\hat{d}_{s,t} + \hat{d}'_{s,t}\hat{d}_{t,s}| \end{aligned} \quad (\text{A.1.23})$$

for all $\epsilon > 0$, where $\hat{d}_{s,t}$ remain to be evaluated. If $w_t = 1$ a.s. (all t),

$$\begin{aligned} \mathbb{E}^\dagger \|\Delta_{00}^{(3)}\|^2 &= \sum_{s,t=k+1}^{T-1} \mathbb{E}^\dagger(\hat{\varepsilon}_{\pi(s)}\hat{\varepsilon}_{\pi(t)} - \varepsilon_{\pi(s)}\varepsilon_{\pi(t)})^2 \{\hat{d}'_{s,t}\hat{d}_{s,t} + \mathbb{I}_{s \neq t}\hat{d}'_{s,t}\hat{d}_{t,s}\} \\ &+ \mathbb{E}^\dagger\{(\hat{\varepsilon}_{\pi(k+1)}\hat{\varepsilon}_{\pi(k+2)} - \varepsilon_{\pi(k+1)}\varepsilon_{\pi(k+2)})(\hat{\varepsilon}_{\pi(k+1)}\hat{\varepsilon}_{\pi(T)} - \varepsilon_{\pi(k+1)}\varepsilon_{\pi(T)})\} \\ &\quad \times \sum_{s,t,v=k+1}^{T-1} \mathbb{I}_{\#\{s,t,v\}=3}(\hat{d}'_{s,t} + \hat{d}'_{s,t})(\hat{d}_{s,v} + \hat{d}_{v,s}) \\ &+ \mathbb{E}^\dagger\{(\hat{\varepsilon}_{\pi(k+1)}\hat{\varepsilon}_{\pi(k+2)} - \varepsilon_{\pi(k+1)}\varepsilon_{\pi(k+2)})(\hat{\varepsilon}_{\pi(T-1)}\hat{\varepsilon}_{\pi(T)} - \varepsilon_{\pi(T-1)}\varepsilon_{\pi(T)})\} \\ &\quad \times \sum_{s,t,u,v=k+1}^{T-1} \mathbb{I}_{\#\{s,t,u,v\}=4}\hat{d}'_{s,t}\hat{d}_{u,v}, \end{aligned}$$

where $|\mathbb{E}^\dagger\{(\hat{\varepsilon}_{\pi(k+1)}\hat{\varepsilon}_{\pi(k+2)} - \varepsilon_{\pi(k+1)}\varepsilon_{\pi(k+2)})(\hat{\varepsilon}_{\pi(k+1)}\hat{\varepsilon}_{\pi(T)} - \varepsilon_{\pi(k+1)}\varepsilon_{\pi(T)})\}|$ equals

$$\begin{aligned} & O(T^{-3}) \left| \sum_{s,t,v=k+1}^T \mathbb{I}_{\#\{s,t,v\}=3}(\hat{\varepsilon}_s\hat{\varepsilon}_t - \varepsilon_s\varepsilon_t)(\hat{\varepsilon}_s\hat{\varepsilon}_v - \varepsilon_s\varepsilon_v) \right| \\ &= O(T^{-3}) \sum_{s=k+1}^T \left[\left\{ \sum_{t=k+1}^T \mathbb{I}_{s \neq t}(\hat{\varepsilon}_s\hat{\varepsilon}_t - \varepsilon_s\varepsilon_t) \right\}^2 - \sum_{t=k+1}^T \mathbb{I}_{s \neq t}(\hat{\varepsilon}_s\hat{\varepsilon}_t - \varepsilon_s\varepsilon_t)^2 \right] \\ &\leq O(T^{-3}) \sum_{s=k+1}^T \left\{ \sum_{t=k+1}^T \mathbb{I}_{s \neq t}(\hat{\varepsilon}_s\hat{\varepsilon}_t - \varepsilon_s\varepsilon_t) \right\}^2 \\ &= O(T^{-3}) \sum_{s=k+1}^T [\hat{\varepsilon}_s^2 \left\{ \sum_{t=k+1}^T \mathbb{I}_{s \neq t}(\hat{\varepsilon}_t - \varepsilon_t) \right\}^2 + (\hat{\varepsilon}_s - \varepsilon_s)^2 \left(\sum_{t=k+1}^T \mathbb{I}_{s \neq t} \varepsilon_t \right)^2] \\ &\leq O(T^{-3}) [\hat{\sigma}_{T_k}^2 \left\{ \sum_{t=k+1}^T (\hat{\varepsilon}_t - \varepsilon_t) \right\}^2 + \|\hat{\varepsilon}_T - \varepsilon_T\|^2 \{\hat{\sigma}_{T_k}^2 + \sigma_T^2 + \left(\sum_{t=k+1}^T \varepsilon_t \right)^2\}] \end{aligned}$$

is $O_P(T^{-3}ka_k^2a_T^{2+\epsilon})$ for all $\epsilon > 0$, using (A.1.14), (A.1.16) and (10), and similarly, $|\mathbb{E}^\dagger\{(\hat{\varepsilon}_{\pi(k+1)}\hat{\varepsilon}_{\pi(k+2)} -$

$\varepsilon_{\pi(k+1)}\varepsilon_{\pi(k+2)}(\hat{\varepsilon}_{\pi(T-1)}\hat{\varepsilon}_{\pi(T)} - \varepsilon_{\pi(T-1)}\varepsilon_{\pi(T)})\}$ equals

$$\begin{aligned}
O(T^{-4}) & \left| \sum_{s,t,u,v=k+1}^T \mathbb{I}_{\#\{s,t,u,v\}=4}(\hat{\varepsilon}_s\hat{\varepsilon}_t - \varepsilon_s\varepsilon_t)(\hat{\varepsilon}_u\hat{\varepsilon}_v - \varepsilon_u\varepsilon_v) \right| \\
& = O(T^{-4}) \left| \left\{ \sum_{s,t=k+1}^T \mathbb{I}_{s \neq t}(\hat{\varepsilon}_s\hat{\varepsilon}_t - \varepsilon_s\varepsilon_t) \right\}^2 \right. \\
& \quad \left. - 4 \sum_{s,t,v=k+1}^T \mathbb{I}_{\#\{s,t,v\}=3}(\hat{\varepsilon}_s\hat{\varepsilon}_t - \varepsilon_s\varepsilon_t)(\hat{\varepsilon}_s\hat{\varepsilon}_v - \varepsilon_s\varepsilon_v) - 2 \sum_{s,t=k+1}^T \mathbb{I}_{s \neq t}(\hat{\varepsilon}_s\hat{\varepsilon}_t - \varepsilon_s\varepsilon_t)^2 \right| \\
& \leq O(T^{-4}) \left\{ \sum_{s,t=k+1}^T \mathbb{I}_{s \neq t}(\hat{\varepsilon}_s\hat{\varepsilon}_t - \varepsilon_s\varepsilon_t) \right\}^2 + O_P(T^{-4}ka_k^2a_T^{2+\epsilon})
\end{aligned}$$

using previous evaluations, so further

$$\begin{aligned}
& = O(T^{-4}) \left\{ \left[\sum_{t=k+1}^T (\hat{\varepsilon}_t - \varepsilon_t) \right]^2 + 2 \sum_{t=k+1}^T \varepsilon_t \sum_{s=k+1}^T (\hat{\varepsilon}_s - \varepsilon_s) + \sum_{t=k+1}^T (\varepsilon_t^2 - \hat{\varepsilon}_t^2) \right\}^2 \\
& \quad + O_P(T^{-4}ka_k^2a_T^{2+\epsilon}) = O(T^{-4}) \left\{ (k^{1/2}a_k a_T^\epsilon + a_T l_T) k^{1/2} a_k a_T^\epsilon \right. \\
& \quad \left. + \|\hat{\varepsilon}_T - \varepsilon_T\|^2 + 2 \|\hat{\varepsilon}_T - \varepsilon_T\| \hat{\sigma}_{Tk} \right\}^2 + O_P(T^{-4}ka_k^2a_T^{2+\epsilon})
\end{aligned}$$

which is $O_P(T^{-4}ka_k^2a_T^{2+\epsilon})$ for all $\epsilon > 0$. Hence,

$$\begin{aligned}
E^\dagger \|\Delta_{00}^{(3)}\|^2 & = O_P(T^{-1}a_k^2a_T^{2+\epsilon}) \sum_{s=k+1}^{T-1} \|\hat{d}_{s,s}\|^2 \\
& \quad + O_P(T^{-2}a_k^2a_T^{2+\epsilon}) \sum_{s,t=k+1}^{T-1} \mathbb{I}_{s \neq t} |\hat{d}'_{s,t} \hat{d}_{s,t} + \hat{d}'_{s,t} \hat{d}_{t,s}| \\
& \quad + O_P(T^{-3}ka_k^2a_T^{2+\epsilon}) \sum_{s,t,v=k+1}^{T-1} \mathbb{I}_{\#\{s,t,v\}=3} |(\hat{d}'_{s,t} + \hat{d}'_{s,t})(\hat{d}_{s,v} + \hat{d}_{v,s})| \\
& \quad + O_P(T^{-4}ka_k^2a_T^{2+\epsilon}) \sum_{s,t,u,v=k+1}^{T-1} \mathbb{I}_{\#\{s,t,u,v\}=4} |\hat{d}'_{s,t} \hat{d}_{u,v}|. \tag{A.1.24}
\end{aligned}$$

We now turn to $c_{s,t}$ and $\hat{d}_{s,t}$. As in the proof of Corollary 1,

$$\begin{aligned}
\|\hat{\gamma}_{T-k-2} - \gamma_{T-k-2}\|_\infty & \leq \|\hat{\gamma}_{T-k-2} - \gamma_{T-k-2}\|_1 \tag{A.1.25} \\
& := \sum_{j=1}^{T-k-2} |\hat{\gamma}_j - \gamma_j| = O_P(\|\hat{\beta}_k - \beta_k\|_1 + \sum_{j=k+1}^{\infty} |\beta_j|),
\end{aligned}$$

$$\begin{aligned}
\|\hat{\gamma}_{T-k-2} - \gamma_{T-k-2}\| & := \left(\sum_{j=1}^{T-k-2} |\hat{\gamma}_j - \gamma_j|^2 \right)^{1/2} \tag{A.1.26} \\
& = O_P(\|\hat{\beta}_k - \beta_k\| + \sum_{j=k+1}^{\infty} |\beta_j|).
\end{aligned}$$

Using also the identity $\|\text{vec}(\mathbf{ab}')\| = \|\mathbf{a}\| \|\mathbf{b}\|$, the triangle inequality and (10), we obtain, for all $\epsilon > 0$ and s, t that

$$\begin{aligned}
\|c_{s,t}\| &= \|\text{vec}\{ \sum_{i=\max\{0,s-t\}}^{T-t-1} (\hat{\gamma}_{t-s+i:k} - \gamma_{t-s+i:k}) \hat{\gamma}'_{i:k} + \gamma_{t-s+i:k} (\hat{\gamma}_{i:k} - \gamma_{i:k})'\} \| \\
&\leq (2\|\gamma\| + \|\hat{\gamma}_{T-k-2} - \gamma_{T+k-2}\|) \\
&\quad \times \sum_{i=\max\{0,s-t\}}^{T-t-1} (\|\hat{\gamma}_{t-s+i:k} - \gamma_{t-s+i:k}\| + \|\hat{\gamma}_{i:k} - \gamma_{i:k}\|) \\
&= O_P(k) \|\hat{\gamma}_{T-k-2} - \gamma_{T-k-2}\| = O_P(ka_k a_T^{\epsilon-1})
\end{aligned}$$

uniformly in s, t . Thus, $E^\dagger \|\Delta_{00}^{(1)}\| = O_P(ka_k a_T^{1+\epsilon})$ and, returning to (A.1.17) and (A.1.21), $E^\dagger \|\Delta_{00}^{(2)}\|^2 = O_P(k^2 a_k^2 a_T^{2+\epsilon})$ for all $\epsilon > 0$.

Further, using (A.1.26), (i),

$$\begin{aligned}
\sum_{s=k+1}^{T-1} \|\hat{d}_{s,s}\|^2 &\leq \sum_{s=k+1}^{T-1} \left(\sum_{i=0}^{T-s-1} \|\hat{\gamma}_{i:k}\|^2 \right)^2 \leq \sum_{s=k+1}^{T-1} \left(k \sum_{i=0}^{T-s-1} |\hat{\gamma}_i|^2 \right)^2 \\
&\leq 2Tk^2 (\|\gamma\|^4 + \|\hat{\gamma}_{T-k-2} - \gamma_{T-k-2}\|^4) = O_P(Tk^2),
\end{aligned}$$

and (ii),

$$\begin{aligned}
\sum_{s,t=k+1}^{T-1} \mathbb{I}_{s \neq t} |\hat{d}'_{s,t} \hat{d}_{s,t} + \hat{d}'_{s,t} \hat{d}_{t,s}| &\leq \sum_{s,t=k+1}^{T-1} \mathbb{I}_{s \neq t} (\|\hat{d}_{s,t}\|^2 + \|\hat{d}_{t,s}\| \|\hat{d}_{s,t}\|) \\
&\leq 2 \sum_{s,t=k+1}^{T-1} \mathbb{I}_{s \neq t} \left(\sum_{i=0}^{T-1-\max\{t,s\}} \|\hat{\gamma}_{|t-s|+i:k}\| \|\hat{\gamma}_{i:k}\| \right)^2 \\
&\leq \|\hat{\gamma}_{T-k-2}\|^2 \sum_{s,t=k+1}^{T-1} \mathbb{I}_{s \neq t} \left(\sum_{i=0}^{T-1-\max\{t,s\}} \|\hat{\gamma}_{|t-s|+i:k}\| \right)^2 \\
&= O(T^2) (\|\gamma\| + \|\hat{\gamma}_{T-k-2} - \gamma_{T-k-2}\|)^2 \left(\sum_{i=0}^{T-k-2} \|\hat{\gamma}_{i:k}\| \right)^2 \\
&= O(k^2 T^2) (\|\gamma\| + \|\hat{\gamma}_{T-k-2} - \gamma_{T-k-2}\|)^4 = O_P(k^2 T^2).
\end{aligned}$$

Before (iii), observe that, by Assumption 1(b), Lemma A.2 and (10),

$$\begin{aligned}
& \sum_{i=1}^{T-k-2} i \|\hat{\gamma}_{i:k}\| \leq \sum_{i=1}^{T-k-2} i \|\hat{\gamma}_{i:k} - \gamma_{i:k}\| + \sum_{i=1}^{T-k-2} i \|\gamma_{i:k}\| \quad (\text{A.1.27}) \\
& \leq \sum_{i=1}^{T-k-2} i \left\{ \sum_{j=0}^{k-1} (\hat{\gamma}_{i-j} - \gamma_{i-j})^2 \right\}^{1/2} + k \sum_{i=1}^{\infty} i |\gamma_i| + k^2 \|\gamma\|_1 \\
& = O_P(\|\hat{\beta}_k - \beta_k\|_1 + \sum_{j=k+1}^{\infty} |\beta_j|) k^{1/2} \sum_{i=1}^{T-k-2} i \left(1 + \frac{1}{k}\right)^{i \wedge k - i - 1} \\
& + \sqrt{2} \sum_{i=1}^{T-k-2} i \sum_{j=0}^{(k-1) \wedge i} |b_{i-j,k}| + O(k^2) \\
& = O_P(\|\hat{\beta}_k - \beta_k\|_1 + \sum_{j=k+1}^{\infty} |\beta_j|) k^{5/2} + O(kT) \sum_{j=k+1}^{\infty} |\beta_j| \\
& + O(k^2) = O_P(k^3 a_k a_T^{\epsilon-1} + kT a_T^{-1} + k^2)
\end{aligned}$$

for all $\epsilon > 0$, so using also (A.1.26) and (10),

$$\begin{aligned}
& \sum_{s,t,v=k+1}^{T-1} \mathbb{I}_{\#\{s,t,v\}=3} |(\hat{d}_{s,t} + \hat{d}_{t,s})'(\hat{d}_{s,v} + \hat{d}_{v,s})| \\
& \leq \sum_{s=k+1}^{T-1} \left(\sum_{t=k+1}^{T-1} \mathbb{I}_{s \neq t} \|\hat{d}_{s,t} + \hat{d}_{t,s}\| \right)^2 \\
& \leq 4 \sum_{s=k+1}^{T-1} \left(\sum_{t=k+1}^{T-1} \mathbb{I}_{s \neq t} \sum_{i=0}^{T-1-\max\{t,s\}} \|\hat{\gamma}_{|t-s|+i:k}\| \|\hat{\gamma}_{i:k}\| \right)^2 \\
& \leq 4 \|\hat{\gamma}_{T-k-2}\|^2 \sum_{s=k+1}^{T-1} \left(\sum_{t=k+1}^{T-1} \mathbb{I}_{s \neq t} \sum_{i=0}^{T-1-\max\{t,s\}} \|\hat{\gamma}_{|t-s|+i:k}\| \right)^2 \\
& \leq 4(\|\gamma\| + \|\hat{\gamma}_{T-k-2} - \gamma_{T-k-2}\|)^2 \sum_{s=k+1}^{T-1} \left(2 \sum_{i=1}^{T-k-2} i \|\hat{\gamma}_{i:k}\| \right)^2 \\
& = O_P(k^4 T + k^6 a_k^2 T a_T^{\epsilon-2} + k^2 T^3 a_T^{-2})
\end{aligned}$$

for all $\epsilon > 0$, and (iv), similarly,

$$\begin{aligned}
& \sum_{s,t,u,v=k+1}^{T-1} \mathbb{I}_{\#\{s,t,u,v\}=4} |\hat{d}'_{s,t} \hat{d}_{u,v}| \leq \left(\sum_{s,t=k+1}^{T-1} \mathbb{I}_{s \neq t} \|\hat{d}_{s,t}\| \right)^2 \\
& \leq \left(\sum_{s,t=k+1}^{T-1} \mathbb{I}_{s \neq t} \sum_{i=0}^{T-1-\max\{t,s\}} \|\hat{\gamma}_{|t-s|+i:k}\| \|\hat{\gamma}_{i:k}\| \right)^2 \\
& \leq \|\hat{\gamma}_{T-k-2}\|^2 \left(\sum_{s,t=k+1}^{T-1} \mathbb{I}_{s \neq t} \sum_{i=0}^{T-1-\max\{t,s\}} \|\hat{\gamma}_{|t-s|+i:k}\| \right)^2 \\
& \leq (\|\gamma\| + \|\hat{\gamma}_{T-k-2} - \gamma_{T-k-2}\|)^2 \left(2 \sum_{s=k+1}^{T-1} \sum_{i=1}^{T-k-2} i \|\hat{\gamma}_i\| \right)^2 \\
& = O_P(k^4 T^2 + k^6 a_k^2 T^2 a_T^{\epsilon-2} + k^2 T^4 a_T^{-2}).
\end{aligned}$$

Thus, returning to (A.1.23) and (A.1.24),

$$\begin{aligned} \mathbf{E}^\dagger \|\Delta_{00}^{(3)}\|^2 &= O_P(k^2 a_k^2 a_T^{2+\epsilon}) \\ &\quad + O_P(T^{-4} k a_k^2 a_T^{2+\epsilon}) O_P(k^4 T^2 + k^6 a_k^2 T^2 a_T^{\epsilon-2} + k^2 T^4 a_T^{-2}) \end{aligned}$$

is $O_P(k^2 a_k^2 a_T^{2+\epsilon})$ for all $\epsilon > 0$, if $k^3/T \rightarrow 0$. As also $\mathbf{E}^\dagger \|\Delta_{00}^{(1)}\| = O_P(k a_k a_T^{1+\epsilon})$ and $\mathbf{E}^\dagger \|\Delta_{00}^{(2)}\|^2 = O_P(k^2 a_k^2 a_T^{2+\epsilon})$ were found to hold, it follows that $\|\Delta_{00}\| = O_{P^\dagger}(k a_k a_T^{1+\epsilon})$ in P -probability for all $\epsilon > 0$, in the case where π is an r.p.

For $\pi = id$ (and Rademacher w_t), $\mathbf{E}^\dagger \|\Delta_{00}^{(1)}\| \leq \sigma_T^2 \max_{t=k+1, \dots, T} \|c_{t,t}\|$ is $O_P(k a_k a_T^{1+\epsilon})$ as previously,

$$\mathbf{E}^\dagger \|\Delta_{00}^{(2)}\|^2 \leq \sum_{s,t=k+1}^{T-1} \varepsilon_s^2 \varepsilon_t^2 \mathbb{I}_{s \neq t} |c'_{s,t} c_{s,t} + c'_{t,s} c_{t,s}| \leq \sigma_T^4 O_P(k^2 a_k^2 a_T^{\epsilon-2})$$

is $O_P(k^2 a_k^2 a_T^{2+\epsilon})$ using the previous uniform estimate of $\|c_{s,t}\|$, and finally,

$$\begin{aligned} \mathbf{E}^\dagger \|\Delta_{00}^{(3)}\|^2 &= \mathbf{E}^\dagger \left\| \sum_{s,t=k+1}^{T-1} w_s w_t (\hat{\varepsilon}_s \hat{\varepsilon}_t - \varepsilon_s \varepsilon_t) \hat{d}_{s,t} \right\|^2 \\ &\leq \sum_{s,t=k+1}^{T-1} (\hat{\varepsilon}_s \hat{\varepsilon}_t - \varepsilon_s \varepsilon_t)^2 \{ \hat{d}'_{s,t} \hat{d}_{s,t} + \hat{d}'_{t,s} \hat{d}_{t,s} \} \\ &\leq \left\{ \sum_{s,t=k+1}^{T-1} (\hat{\varepsilon}_s \hat{\varepsilon}_t - \varepsilon_s \varepsilon_t)^2 \right\} \left(\max_{s,t=k+1, \dots, T-1} \|\hat{d}_{s,t}\| \right)^2, \end{aligned}$$

where $\sum_{s,t=k+1}^{T-1} (\hat{\varepsilon}_s \hat{\varepsilon}_t - \varepsilon_s \varepsilon_t)^2 = O_P(a_k^2 a_T^{2+\epsilon})$ for $\epsilon > 0$ as in (A.1.22) and

$$\begin{aligned} \|\hat{d}_{s,t}\| &\leq \sum_{i=\max\{0, s-t\}}^{T-t-1} \|\mathbf{G}_{t-s+i, i:k}\| + \|c_{s,t}\| \\ &\leq \sum_{i=\max\{0, s-t\}}^{T-t-1} \|\gamma_{t-s+i:k}\| \|\gamma_{i:k}\| + \|c_{s,t}\| \leq k \|\gamma\|^2 + O_P(k a_k a_T^{\epsilon-1}) \end{aligned}$$

is $O_P(k)$ uniformly in s, t , so also $\mathbf{E}^\dagger \|\Delta_{00}^{(3)}\|^2 = O_P(k^2 a_k^2 a_T^{2+\epsilon})$ for every $\epsilon > 0$. By combining the evaluations of $\|\Delta_{00}^{(i)}\|$ ($i = 1, 2, 3$) and applying Markov's inequality, the first statement in part (a) is proved also for the wild bootstrap scheme.

Regarding the lower bound for $S_{00}^{\dagger k}$, let

$$\begin{aligned} \tau &:= \min\{t : k+1 \leq t \leq T, |\varepsilon_t| = \max_{k+1 \leq s \leq T} |\varepsilon_s|\}, \\ \mathcal{T} &:= \{\tau = \min\{t : k+1 \leq t \leq T, |\varepsilon_t| = \max_{k+1 \leq s \leq T-1} |\varepsilon_{\pi(s)}|\}\}; \end{aligned}$$

then $P(\mathcal{T}) \rightarrow 1$. By considerations of positive semi-definiteness, for outcomes in \mathcal{T} it holds that

$$\lambda_{\min}(S_{00}^{\dagger k}) \geq \lambda_{\min} \left(\varepsilon_\tau^2 \sum_{j=0}^{T-\pi^{-1}(\tau)-1} \gamma_{j:k} \gamma'_{j:k} + \varepsilon_\tau w_{\pi^{-1}(\tau)} \Delta_\lambda \right), \quad (\text{A.1.28})$$

where the right-hand side matrix collects the terms of $S_{00}^{\dagger k}$ involving ε_τ , with

$$\Delta_\lambda := \sum_{t=k+1}^{T-1} \mathbb{I}_{\tau \neq \pi(t)} w_t \varepsilon_{\pi(t)} (d_{\pi^{-1}(\tau), t} + d_{t, \pi^{-1}(\tau)}),$$

$d_{s,t} := \sum_{i=\max\{0,s-t\}}^{T-t-1} \gamma_{t-s+i:k} \gamma'_{i:k}$. We evaluate Δ_λ for the three bootstrap schemes.
If π is an r.p., then

$$\begin{aligned} \mathbb{E}^\dagger \|\Delta_\lambda\|^2 &= \sum_{t=k+1}^{T-1} \mathbb{E}^\dagger (\mathbb{I}_{\tau \neq \pi(t)} \varepsilon_{\pi(t)}^2 \|d_{\pi^{-1}(\tau),t} + d_{t,\pi^{-1}(\tau)}\|^2) \\ &\quad + \sum_{t,s=k+1}^{T-1} \mathbb{E}^\dagger [\mathbb{I}_{\pi(t) \neq \tau \neq \pi(s), t \neq s} w_t w_s \varepsilon_{\pi(t)} \varepsilon_{\pi(s)} \\ &\quad \times \text{tr}\{(d_{\pi^{-1}(\tau),t} + d_{t,\pi^{-1}(\tau)})'(d_{\pi^{-1}(\tau),s} + d_{s,\pi^{-1}(\tau)})\}]. \end{aligned}$$

Next, if further w_t are Rademacher, this reduces to

$$\begin{aligned} \mathbb{E}^\dagger \|\Delta_\lambda\|^2 &= \sum_{t=k+1}^{T-1} \mathbb{E}^\dagger (\mathbb{I}_{\tau \neq \pi(t)} \varepsilon_{\pi(t)}^2 \|d_{\pi^{-1}(\tau),t} + d_{t,\pi^{-1}(\tau)}\|^2) \\ &= \sum_{t=k+1}^{T-1} \mathbb{E}^\dagger \left(\sum_{u,v=k+1}^T \mathbb{I}_{t \neq v} \mathbb{I}_{\pi(t)=u, \pi(v)=\tau} \varepsilon_u^2 \|d_{v,t} + d_{t,v}\|^2 \right) \\ &= \sum_{t=k+1}^{T-1} \sum_{u,v=k+1}^T \mathbb{I}_{t \neq v} \mathbb{P}^\dagger(\pi(t) = u, \pi(v) = \tau) \varepsilon_u^2 \|d_{v,t} + d_{t,v}\|^2 \\ &= O(T^{-2}) \sum_{t=k+1}^{T-1} \sum_{u,v=k+1}^T \mathbb{I}_{t \neq v} \mathbb{I}_{u \neq \tau} \varepsilon_u^2 \|d_{v,t} + d_{t,v}\|^2 \\ &= O(T^{-2}) \sigma_T^2 \sum_{v=k+1}^T \sum_{t=k+1}^{T-1} \mathbb{I}_{t \neq v} \|d_{v,t} + d_{t,v}\|^2 \end{aligned}$$

because $\mathbb{P}^\dagger(\pi(t) = u, \pi(v) = \tau) = (T-k)^{-1}(T-k-1)^{-1}$ for $t \neq v, u \neq \tau$ (τ is \dagger -measurable). Further,

$$\begin{aligned} \sum_{t=k+1}^{T-1} \mathbb{I}_{t \neq v} \|d_{v,t}\|^2 &\leq \sum_{t=k+1}^{T-1} \mathbb{I}_{t \neq v} \left\| \sum_{i=\max\{0,v-t\}}^{T-t-1} \gamma_{t-v+i:k} \gamma'_{i:k} \right\|^2 \\ &\leq 2k \|\gamma\|^2 (k^2 \|\gamma\|^2 + k \sum_{i=1}^{\infty} i \gamma_i^2) = O(k^3) \end{aligned} \tag{A.1.29}$$

and similarly for $\sum_{t=k+1}^{T-1} \mathbb{I}_{t \neq v} \|d_{t,v}\|^2$, so for the permuted wild bootstrap, $\mathbb{E}^\dagger \|\Delta_\lambda\|^2 = O_P(T^{-1}k^3) \sigma_T^2 = O_P(T^{-1}k^3 a_T^2) = O_P(a_T^2)$ as $k^3/T \rightarrow 0$, and $\|\Delta_\lambda\| = O_P(a_T)$ in P -probability. If $w_t = 1$ a.s. (all t), the estimate of $\sum_{t=k+1}^{T-1} \mathbb{E}^\dagger (\mathbb{I}_{\tau \neq \pi(t)} \varepsilon_{\pi(t)}^2 \|d_{\pi^{-1}(\tau),t} + d_{t,\pi^{-1}(\tau)}\|^2)$ remains valid. Additionally,

$$\begin{aligned} &\mathbb{E}^\dagger [\mathbb{I}_{\pi(t) \neq \tau \neq \pi(s), t \neq s} \varepsilon_{\pi(t)} \varepsilon_{\pi(s)} \text{tr}\{(d_{\pi^{-1}(\tau),t} + d_{t,\pi^{-1}(\tau)})'(d_{\pi^{-1}(\tau),s} + d_{s,\pi^{-1}(\tau)})\}] \\ &= \mathbb{E}^\dagger \sum_{u,v,w=k+1}^T \mathbb{I}_{\#\{t,s,w\}=3} \mathbb{I}_{\pi(t)=u, \pi(s)=v, \pi(w)=\tau} \varepsilon_u \varepsilon_v \\ &\quad \times \text{tr}\{(d_{w,t} + d_{t,w})'(d_{w,s} + d_{s,w})\} \\ &= \sum_{u,v,w=k+1}^T \mathbb{I}_{\#\{t,s,w\}=3} \mathbb{P}^\dagger(\pi(t) = u, \pi(s) = v, \pi(w) = \tau) \\ &\quad \times \varepsilon_u \varepsilon_v \text{tr}\{(d_{w,t} + d_{t,w})'(d_{w,s} + d_{s,w})\} \end{aligned}$$

$$\begin{aligned}
&= O(T^{-3}) \sum_{u,v=k+1}^T \varepsilon_u \varepsilon_v \mathbb{I}_{\#\{u,v,\tau\}=3} \sum_{w=k+1}^T \mathbb{I}_{\#\{t,s,w\}=3} \\
&\quad \times \text{tr}\{(d_{w,t} + d_{t,w})'(d_{w,s} + d_{s,w})\}
\end{aligned}$$

uniformly in t, s because $P^\dagger(\pi(t) = u, \pi(s) = v, \pi(w) = \tau) = O(T^{-3})\mathbb{I}_{\#\{u,v,\tau\}=3}$ for $\#\{t, s, w\} = 3$. Hence,

$$\begin{aligned}
& \left| \sum_{t,s=k+1}^{T-1} E^\dagger[\mathbb{I}_{\pi(t) \neq \tau \neq \pi(s), t \neq s} \varepsilon_{\pi(t)} \varepsilon_{\pi(s)} \text{tr}\{(d_{\pi^{-1}(\tau),t} + d_{t,\pi^{-1}(\tau)})'(d_{\pi^{-1}(\tau),s} + d_{s,\pi^{-1}(\tau)})\}] \right| \\
& \leq O(T^{-3}) \left[\left(\sum_{u=k+1}^T \varepsilon_u \right)^2 + \sigma_T^2 \right] \sum_{w=k+1}^T \left| \sum_{t,s=k+1}^{T-1} \mathbb{I}_{\#\{t,s,w\}=3} \right. \\
& \quad \left. \times \text{tr}\{(d_{w,t} + d_{t,w})'(d_{w,s} + d_{s,w})\} \right|
\end{aligned}$$

is $O_P(T^{-2}k^4 a_T^2 l_T) = o_P(a_T^2)$ for $k^3/T \rightarrow 0$, since

$$\begin{aligned}
& \left| \sum_{t,s=k+1}^{T-1} \mathbb{I}_{\#\{t,s,w\}=3} \text{tr}\{(d_{w,t} + d_{t,w})'(d_{w,s} + d_{s,w})\} \right| \\
& \leq 2^4 \|\gamma\|^2 (k^2 \|\gamma\|_1 + k \sum_{i=1}^{\infty} i |\gamma_i|)^2 = O(k^4).
\end{aligned}$$

Therefore, $E^\dagger \|\Delta_\lambda\|^2 = o_P(a_T^2)$, and $\|\Delta_\lambda\| = o_{P^\dagger}(a_T)$ in P -probability, also for the permutation bootstrap.

For π equal to the identity (wild bootstrap), it holds that

$$E^\dagger \|\Delta_\lambda\|^2 = \sum_{t=k+1}^{T-1} \mathbb{I}_{\tau \neq t} \varepsilon_t^2 \|d_{\tau,t} + d_{t,\tau}\|^2, \quad (\text{A.1.30})$$

where

$$\begin{aligned}
& E \sum_{t=k+1}^{T-1} \mathbb{I}_{\tau \neq t} \mathbb{I}_{|\varepsilon_t| \leq a_T} \varepsilon_t^2 \|d_{\tau,t} + d_{t,\tau}\|^2 \quad (\text{A.1.31}) \\
& = E E \left(\sum_{t=k+1}^{T-1} \mathbb{I}_{\tau \neq t} \mathbb{I}_{|\varepsilon_t| \leq a_T} \varepsilon_t^2 \|d_{\tau,t} + d_{t,\tau}\|^2 \middle| \tau \right) \\
& = E \sum_{t=k+1}^{T-1} \mathbb{I}_{\tau \neq t} E(\mathbb{I}_{|\varepsilon_t| \leq a_T} \varepsilon_t^2 | \tau) \|d_{\tau,t} + d_{t,\tau}\|^2 \\
& \leq E(\mathbb{I}_{|\varepsilon_1| \leq a_T} \varepsilon_1^2) E \sum_{t=k+1}^{T-1} \mathbb{I}_{\tau \neq t} \|d_{\tau,t} + d_{t,\tau}\|^2
\end{aligned}$$

is $O(T^{-1}k^3 a_T^2) = o(a_T^2)$ because $\mathbb{I}_{\tau \neq t} E(\mathbb{I}_{|\varepsilon_t| \leq a_T} \varepsilon_t^2 | \tau) \leq \mathbb{I}_{\tau \neq t} E(\mathbb{I}_{|\varepsilon_t| \leq a_T} \varepsilon_t^2) = \mathbb{I}_{\tau \neq t} E(\mathbb{I}_{|\varepsilon_1| \leq a_T} \varepsilon_1^2)$ a.s. by the maximizing property of τ , $E(\mathbb{I}_{|\varepsilon_t| \leq a_T} \varepsilon_t^2) = O(T^{-1}a_T^2)$ by KT,

$$\sum_{t=k+1}^{T-1} \mathbb{I}_{\tau \neq t} \|d_{\tau,t} + d_{t,\tau}\|^2 \leq 4k \|\gamma\|^2 (k^2 \|\gamma\|^2 + k \sum_{i=1}^{\infty} i \gamma_i^2) = O(k^3)$$

with a deterministic bound (see equation (A.1.29)), and $k^3/T \rightarrow 0$; similarly,

$$\begin{aligned} & \mathbb{E} \left(\sum_{t=k+1}^{T-1} \mathbb{I}_{\tau \neq t} \mathbb{I}_{|\varepsilon_t| > a_T} \varepsilon_t^2 \|d_{\tau,t} + d_{t,\tau}\|^2 \right)^{\eta/2} \\ & \leq \mathbb{E}(\mathbb{I}_{|\varepsilon_1| > a_T} |\varepsilon_1|^\eta) \mathbb{E} \sum_{t=k+1}^{T-1} \mathbb{I}_{\tau \neq t} \|d_{\tau,t} + d_{t,\tau}\|^\eta \end{aligned}$$

is $O(T^{-1}k^2a_T^\eta) = o(a_T^\eta)$ for $\eta \in [\delta, \alpha]$ and δ from Assumption 1(b), by KT and since, with a deterministic upper bound and $k^2/T \rightarrow 0$,

$$\sum_{t=k+1}^{T-1} \mathbb{I}_{\tau \neq t} \|d_{\tau,t} + d_{t,\tau}\|^\eta \leq O(1) \left(k^2 \sum_{i=0}^{\infty} |\gamma_i|^\eta + k \sum_{i=1}^{\infty} i |\gamma_i|^\eta \right) = O(k^2),$$

so $\sum_{t=k+1}^{T-1} \mathbb{I}_{\tau \neq t} \mathbb{I}_{|\varepsilon_t| > a_T} \varepsilon_t^2 \|d_{\tau,t} + d_{t,\tau}\|^2 = o_P(a_T^2)$. Recalling also (A.1.30) and (A.1.31), it follows that $\|\Delta_\lambda\| = o_{P^\dagger}(a_T)$ in P -probability also for the wild bootstrap.

By Weyl's inequality (Seber, 2008, p.117), the estimate of $\|\Delta_\lambda\|$ yields

$$\begin{aligned} & \left| \lambda_{\min} \left(\varepsilon_\tau^2 \sum_{j=0}^{T-\pi^{-1}(\tau)-1} \gamma_{j:k} \gamma'_{j:k} + \varepsilon_\tau w_{\pi^{-1}(\tau)} \Delta_\lambda \right) \right. \\ & \left. - \varepsilon_\tau^2 \lambda_{\min} \left(\sum_{j=0}^{T-\pi^{-1}(\tau)-1} \gamma_{j:k} \gamma'_{j:k} \right) \right| \leq |\varepsilon_\tau| \|\Delta_\lambda\| = o_{P^\dagger}(a_T^2) \end{aligned} \quad (\text{A.1.32})$$

in P -probability, because $a_T^{-1} \varepsilon_\tau$ converges in distribution under P . Again by Weyl's inequality and matrix symmetry,

$$\begin{aligned} & \left| \lambda_{\min} \left(\sum_{j=0}^{T-\pi^{-1}(\tau)-1} \gamma_{j:k} \gamma'_{j:k} \right) - \lambda_{\min}(\Sigma_k) \right| \leq \left\| \sum_{j=T-\pi^{-1}(\tau)}^{\infty} \gamma_{j:k} \gamma'_{j:k} \right\|_2 \\ & \leq \sum_{j=T-\pi^{-1}(\tau)}^{\infty} \|\gamma_{j:k} \gamma'_{j:k}\|_1 \leq k (\max_i |\gamma_i|) \sum_{j=\max\{0, T-\pi^{-1}(\tau)-k+1\}}^{\infty} |\gamma_j| \end{aligned}$$

is $o_{P^\dagger}(1)$ in P -probability, the magnitude order because $P^\dagger(T - \pi^{-1}(\tau) - k + 1 \geq k) \xrightarrow{P} 1$ and $k \sum_{j=k}^{\infty} |\gamma_j| \leq \sum_{j=k}^{\infty} j |\gamma_j| \rightarrow 0$ as $k \rightarrow \infty$ as the tail of a convergent series. Since $\lambda_{\min}(\Sigma_k)$ is bounded away from zero, it follows that $\lambda_{\min}(\sum_{j=0}^{T-\pi^{-1}(\tau)-1} \gamma_{j:k} \gamma'_{j:k})$ is bounded away from zero in P^\dagger -probability, and as further $a_T^{-1} \varepsilon_\tau$ converges weakly under P to a distribution with no atom at zero, it follows that $\lambda_{\min}(a_T^{-2} \varepsilon_\tau^2 \sum_{j=0}^{T-\pi^{-1}(\tau)-1} \gamma_{j:k} \gamma'_{j:k})$ is bounded away from zero in P^\dagger , then P , probability. Recalling (A.1.28) and (A.1.32), we can conclude that also $\lambda_{\min}(a_T^{-2} S_{00}^{\dagger k})$ is bounded away from zero in P^\dagger , then P , probability.

PROOF OF PART (B) Write $S_{0\varepsilon}^{*k} - S_{0\varepsilon}^{\dagger k} = \sigma_1 + \sigma_2^* - \sigma_2^\dagger + \sigma_3$ with $\sigma_2^* := \sum_{t=k+1}^T \mathbf{X}_{t-1}^{*k} \rho_{\pi(t),k} w_t$, $\sigma_2^\dagger := \sum_{t=k+1}^T \mathbf{X}_{t-1}^{\dagger k} \rho_{\pi(t),k}^\dagger$ and

$$\begin{aligned} \sigma_3 &: = \sum_{t=k+1}^T (\mathbf{X}_{t-1}^{*k} - \mathbf{X}_{t-1}^{\dagger k}) \varepsilon_{\pi(t)} w_t \\ &= \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} (\hat{\gamma}_{j:k} - \gamma_{j:k}) \hat{\varepsilon}_{\pi(t-j-1)} \varepsilon_{\pi(t)} w_{t-j-1} w_t \\ &\quad + \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \gamma_{j:k} (\hat{\varepsilon}_{\pi(t-j-1)} - \varepsilon_{\pi(t-j-1)}) \varepsilon_{\pi(t)} w_{t-j-1} w_t. \end{aligned}$$

If π is an r.p., we discuss $\sigma_1 + \sigma_2^*$, σ_2^\dagger and σ_3 , no matter how w_t are specified, whereas if π is the identity, we evaluate σ_2^* , σ_2^\dagger and σ_3 .

Let π be the identity (and w_t be Rademacher). For the discussion of σ_2^* , define modified $\rho_{t,kj} := \rho_{t,k} - \varepsilon_{t-j-1} \sum_{i=k+1}^{j+1} \beta_i \gamma_{j+1-i}$, ($j = k, \dots, T-k-2$), as $\rho_{t,k}$ 'cleaned' from the contribution of ε_{t-j-1} , and $\rho_{t,kj} := \rho_{t,k}$ for $j = 0, \dots, k-1$. It holds that

$$\begin{aligned} \mathbf{E}^\dagger \|\sigma_2^*\|^2 &= \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\hat{\gamma}_{j:k}\|^2 \hat{\varepsilon}_{t-j-1}^2 \rho_{t,k}^2 \\ &\leq 4 \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} (\|\gamma_{j:k}\|^2 + \|\hat{\gamma}_{j:k} - \gamma_{j:k}\|^2) (\varepsilon_{t-j-1}^2 + (\hat{\varepsilon}_{t-j-1} - \varepsilon_{t-j-1})^2) \rho_{t,k}^2 \\ &\leq 8 \left(\sum_{t=k+2}^T \sum_{j=k}^{t-k-2} \|\gamma_{j:k}\| \varepsilon_{t-j-1}^2 \left| \sum_{i=k+1}^{j+1} \beta_i \gamma_{j+1-i} \right| \right)^2 \\ &\quad + 8 \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\gamma_{j:k}\|^2 \varepsilon_{t-j-1}^2 \rho_{t,kj}^2 + 4 \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\hat{\gamma}_{j:k} - \gamma_{j:k}\|^2 \varepsilon_{t-j-1}^2 \rho_{t,k}^2 \\ &\quad + 4 \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} (\|\gamma_{j:k}\|^2 + \|\hat{\gamma}_{j:k} - \gamma_{j:k}\|^2) (\hat{\varepsilon}_{t-j-1} - \varepsilon_{t-j-1})^2 \rho_{t,k}^2 \\ &=: 8(\varsigma^2 + \sigma_{21}^*) + 4(\sigma_{22}^* + \sigma_{23}^*). \end{aligned}$$

Here

$$\begin{aligned} \varsigma &= \sum_{t=k+2}^T \sum_{j=k}^{t-k-2} \|\gamma_{j:k}\| \varepsilon_{t-j-1}^2 (\mathbb{I}_{\{|\varepsilon_{t-j-1}| \leq a_T\}} + \mathbb{I}_{\{|\varepsilon_{t-j-1}| > a_T\}}) \left| \sum_{i=k+1}^{j+1} \beta_i \gamma_{j+1-i} \right| \\ &:= \varsigma^{\leq} + \varsigma^{>} = o_P(a_T) \end{aligned}$$

by Markov's inequality, since

$$\begin{aligned} \mathbf{E}(\varsigma^{\leq}) &\leq T \mathbf{E}(\varepsilon_1^2 \mathbb{I}_{\{|\varepsilon_1| \leq a_T\}}) \|\gamma\| \sum_{j=k}^{T-k-2} \|\gamma_{j:k}\| \sum_{i=k+1}^{\infty} |\beta_i| \\ &\leq T \mathbf{E}(\varepsilon_1^2 \mathbb{I}_{\{|\varepsilon_1| \leq a_T\}}) \|\gamma\| \left(\sum_{i=1}^{\infty} i |\gamma_i| + k \sum_{i=k+1}^{\infty} |\gamma_i| \right) \sum_{i=k+1}^{\infty} |\beta_i| = o_P(a_T) \end{aligned}$$

by KT, Assumption 1(b) and the condition $\sum_{i=k+1}^{\infty} |\beta_i| = o(a_T^{-1})$ and, for $\eta \in [\delta, \alpha)$, by using the same facts,

$$\begin{aligned} \mathbb{E} |\varsigma^>|^{\frac{\eta}{2}} &\leq T \mathbb{E} (|\varepsilon_1|^{\eta} \mathbb{I}_{\{|\varepsilon_1| > a_T\}}) \|\gamma\|^{\frac{\eta}{2}} \sum_{j=k}^{T-k-2} \|\gamma_{j:k}\|^{\frac{\eta}{2}} \left(\sum_{i=k+1}^{\infty} |\beta_i| \right)^{\frac{\eta}{2}} \\ &\leq T \mathbb{E} (|\varepsilon_1|^{\eta} \mathbb{I}_{\{|\varepsilon_1| > a_T\}}) \|\gamma\|^{\frac{\eta}{2}} \left(\sum_{i=1}^{\infty} i |\gamma_i|^{\frac{\eta}{2}} + k \sum_{i=k+1}^{\infty} |\gamma_i|^{\frac{\eta}{2}} \right) \left(\sum_{i=k+1}^{\infty} |\beta_i| \right)^{\frac{\eta}{2}} \end{aligned}$$

is $o_P(a_T^{\eta/2})$. Further, for $\eta \in [\delta, \alpha)$ and all t , by independence of ε_{t-j-1} and $\rho_{t,kj}$,

$$\mathbb{E} (\sigma_{21}^*)^{\frac{\eta}{2}} \leq \mathbb{E} |\varepsilon_1|^{\eta} \left(\sup_{t,j} \mathbb{E} |\rho_{t,kj}|^{\eta} \right) \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\gamma_{j:k}\|^{\eta},$$

where the sup is over $t = k+2, \dots, T$ and $j = 0, \dots, t-k-2$. By Hölder's inequality, for $\alpha > 1$ and $\eta \in [1, \alpha)$ it holds that

$$\begin{aligned} \mathbb{E} |\rho_{t,kj}|^{\eta} &= \mathbb{E} |\rho_{k+1,k}|^{\eta} \leq \left(\sum_{i=k+1}^{\infty} |\beta_i| \right)^{\eta-1} \sum_{i=k+1}^{\infty} |\beta_i| \mathbb{E} |X_{k+1-i}|^{\eta} \\ &= \left(\sum_{i=k+1}^{\infty} |\beta_i| \right)^{\eta} \mathbb{E} |X_1|^{\eta} = o(a_T^{-\eta}) \end{aligned}$$

if $j = 0, \dots, k-1$, and similarly,

$$\begin{aligned} \mathbb{E} |\rho_{t,kj}|^{\eta} &\leq \left(\sum_{i=k+1}^{\infty} |\beta_i| \right)^{\eta-1} \sum_{i=k+1}^{\infty} |\beta_i| \mathbb{E} \left| \sum_{l=0}^{\infty} \mathbb{I}_{l \neq j+1} \gamma_l \varepsilon_{t-l} \right|^{\eta} \\ &\leq \left(\sum_{i=k+1}^{\infty} |\beta_i| \right)^{\eta} \|\gamma\|^{\eta} \mathbb{E} |\varepsilon_1|^{\eta} = o(a_T^{-\eta}) \end{aligned}$$

for $j = k, \dots, t-k-2$. Hence, a common, in t and j , $o(a_T^{-\eta})$ upper bound exists for $\mathbb{E} |\rho_{t,kj}|^{\eta}$, yielding

$$\mathbb{E} (\sigma_{21}^*)^{\frac{\eta}{2}} \leq o(kT a_T^{-\eta}) \left(\sum_{j=0}^{\infty} |\gamma_j|^{\eta} \right) = o(kT a_T^{-\eta}), \quad \eta \in [1, \alpha).$$

As $k^2/T \rightarrow 0$, this yields $\sigma_{21}^* = o_P(a_T^2)$. On the other hand, for $\alpha \leq 1$ and $\eta \in [\delta, \alpha)$ it holds that $\mathbb{E} |\rho_{t,kj}|^{\eta} = \mathbb{E} |\rho_{k+1,k}|^{\eta} \leq \mathbb{E} |X_1|^{\eta} \sum_{i=k+1}^{\infty} |\beta_i|^{\eta}$ if $j = 0, \dots, k-1$, and

$$\mathbb{E} |\rho_{t,kj}|^{\eta} \leq \sum_{i=k+1}^{\infty} |\beta_i|^{\eta} \mathbb{E} \left| \sum_{l=0}^{\infty} \mathbb{I}_{l \neq j+1} \gamma_l \varepsilon_{t-l} \right|^{\eta} \leq \mathbb{E} |\varepsilon_1|^{\eta} \sum_{i=0}^{\infty} |\gamma_i|^{\eta} \sum_{i=k+1}^{\infty} |\beta_i|^{\eta}$$

if $j = k, \dots, t-k-2$, so $\mathbb{E} (\sigma_{21}^*)^{\eta/2} = O(kT \sum_{i=k+1}^{\infty} |\beta_i|^{\eta} \sum_{j=k+1}^{\infty} |\gamma_j|^{\eta})$ and, by (A.1.2) and Markov's inequality, $\sigma_{21}^* = o_P(\tilde{a}_T^2)$ under $k^3/T \rightarrow 0$.

Next,

$$\sigma_{22}^* \leq \sigma_T^2 S_{\rho\rho}^k \sum_{j=0}^{T-k-2} \|\hat{\gamma}_{j:k} - \gamma_{j:k}\|^2 = o_P(l_T a_T^2) \sum_{j=0}^{T-k-2} \sum_{i=0}^{k-1} |\hat{\gamma}_{j-i} - \gamma_{j-i}|^2$$

since $S_{\rho\rho}^k = o_P(l_T)$ was proved in the preparation, so from (A.1.12) and (10), for all $\epsilon > 0$,

$$\begin{aligned}\sigma_{22}^* &= o_P(kl_T a_T^2) \{ \|\hat{\boldsymbol{\beta}}_k - \boldsymbol{\beta}_k\|_1^2 + \left(\sum_{j=k+1}^{\infty} |\beta_j| \right)^2 \sum_{j=0}^{\infty} \left(1 + \frac{1}{k} \right)^{-2j} + \sum_{j=0}^{\infty} b_{jk}^2 \} \\ &= o_P(kl_T a_T^2) \{ k^2 a_k^2 a_T^{\epsilon-2} + \left(\sum_{j=k+1}^{\infty} |\beta_j| \right)^2 \} = o_P(k^3 a_k^2 T^\epsilon) = o_P(\tilde{a}_T^2)\end{aligned}$$

if $k^4/T \rightarrow 0$ by choosing small $\epsilon > 0$, and similarly, from (A.1.16) and (10),

$$\begin{aligned}\sigma_{23}^* &\leq \|\hat{\boldsymbol{\varepsilon}}_T - \boldsymbol{\varepsilon}_T\|^2 S_{\rho\rho}^k \sum_{j=0}^{T-k-2} (\|\gamma_{j:k}\|^2 + \|\hat{\gamma}_{j:k} - \gamma_{j:k}\|^2) \\ &= o_P(kl_T a_T^2) \|\hat{\boldsymbol{\beta}}_k - \boldsymbol{\beta}_k\|^2 (\|\boldsymbol{\gamma}\|^2 + o_P(1)) = o_P(\tilde{a}_T^2)\end{aligned}$$

if $k^2/T \rightarrow 0$. We conclude that $\mathbf{E}^\dagger \|\sigma_2^*\|^2 = o_P(\tilde{a}_T^2)$ if $k^4/T \rightarrow 0$ and, hence, $\|\sigma_2^*\| = o_{P^\dagger}(\tilde{a}_T)$ in P -probability if π is the identity.

Regarding $\sigma_2^\dagger = \sum_{t=k+1}^T \mathbf{X}_{t-1}^{\dagger k} \rho_{t,k}^\dagger$ ($\rho_{t,k}^\dagger = \sum_{i=k+1}^{t-k-1} \beta_i \mathbf{X}_{t-i}^\dagger$), we reuse several steps of the evaluation of $\|\sum_{t=k+1}^T \mathbf{X}_{t-1}^k \rho_{t,k}\|$ in the proof of Lemma 2. Namely, all the evaluations of expressions in $|\varepsilon_t|$ and ε_t^2 (equal to $|\varepsilon_t^\dagger|$ and $(\varepsilon_t^\dagger)^2$, resp.) can be used as there, upon replacement of ε_t ($t \leq k$) by zeroes. A minor modification is needed only for (what is now)

$$\begin{aligned}\xi_{ij}^{\leq, \dagger} &: = \sum_{t=k+1+\max\{i,j\}}^{T-1} \sum_{u=0}^{t-i-k-1} \sum_{v=0}^{t-j-k-1} \mathbb{I}_{\{u \neq v+j-i\}} \\ &\quad \times \mathbb{I}_{|\varepsilon_{t-i-u} \varepsilon_{t-j-v}| \leq \tilde{a}_T} \varepsilon_{t-i-u}^\dagger \varepsilon_{t-j-v}^\dagger \gamma_u \gamma_v\end{aligned}$$

with

$$\begin{aligned}\mathbf{E}^\dagger (\xi_{ij}^{\leq, \dagger})^2 &\leq 2\|\boldsymbol{\gamma}\|^2 \sum_{t=k+1+\max\{i,j\}}^{T-1} \sum_{u=0}^{t-i-k-1} \sum_{v=0}^{t-j-k-1} \mathbb{I}_{\{u \neq v+j-i\}} \\ &\quad \times \mathbb{I}_{|\varepsilon_{t-i-u} \varepsilon_{t-j-v}| \leq \tilde{a}_T} \varepsilon_{t-i-u}^2 \varepsilon_{t-j-v}^2 |\gamma_u| |\gamma_v|\end{aligned}$$

possessing, by KT, $\mathbf{E} \mathbf{E}^\dagger (\xi_{ij}^{\leq, \dagger})^2 \leq O(\tilde{a}_T^2) \|\boldsymbol{\gamma}\|^4$ uniformly in i, j , so in place of (A.1.11),

$$\mathbf{E} \mathbf{E}^\dagger \left(\sum_{i=1}^k \left(\sum_{j=k+1}^{\infty} \beta_j \xi_{ij}^{\leq, \dagger} \right)^2 \right) \leq \left[\sum_{i=1}^k \sum_{j=k+1}^{\infty} |\beta_j| \mathbf{E} \mathbf{E}^\dagger \{ (\xi_{ij}^{\leq, \dagger})^2 \} \right] \left(\sum_{j=k+1}^{\infty} |\beta_j| \right)$$

is $O(k\tilde{a}_T^2) (\sum_{j=k+1}^{\infty} |\beta_j|)^2$. Thus, as in the discussion of $\|\sum_{t=k+1}^T \mathbf{X}_{t-1}^k \rho_{t,k}\|$ in Lemma 2, we conclude that $\|\sum_{t=k+1}^T \mathbf{X}_{t-1}^{\dagger k} \rho_{t,k}^\dagger\| = O_{P^\dagger}(a_T^2) \sum_{j=k+1}^{\infty} |\beta_j| = o_{P^\dagger}(a_T)$ in P -probability.

Further,

$$\begin{aligned}\mathbf{E}^\dagger \|\sigma_3\|^2 &\leq 4 \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\hat{\gamma}_{j:k} - \gamma_{j:k}\|^2 \underbrace{\{\varepsilon_{t-j-1,k}^2 + (\hat{\varepsilon}_{t-j-1} - \varepsilon_{t-j-1,k})^2\}}_{=: e_{tj}} \varepsilon_t^2 \\ &\quad + 4 \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\gamma_{j:k}\|^2 \{ (\hat{\varepsilon}_{t-j-1} - \varepsilon_{t-j-1,k})^2 + \rho_{t-j-1,k}^2 \} \varepsilon_t^2 := 4(\sigma_{31} + \sigma_{32} + \sigma_{33}).\end{aligned}$$

First,

$$\begin{aligned}
\sigma_{31} &= \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\hat{\gamma}_{j:k} - \gamma_{j:k}\|^2 e_{tj} = \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \sum_{i=0}^{k-1} (\hat{\gamma}_{j-i} - \gamma_{j-i})^2 e_{tj} \\
&\leq k O_P(\|\hat{\beta}_k - \beta_k\|_1^2 + (\sum_{j=k}^{\infty} |\beta_j|)^2) \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \left(1 + \frac{1}{k}\right)^{-2j} e_{tj} \\
&\quad + 2 \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \sum_{i=0}^{(k-1) \wedge j} b_{j-i,k}^2 e_{tj}
\end{aligned}$$

contains, (i),

$$\begin{aligned}
\sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \left(1 + \frac{1}{k}\right)^{-2j} e_{tj} &\leq 2 \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \left(1 + \frac{1}{k}\right)^{-2j} \{\varepsilon_{t-j-1}^2 + \rho_{t-j-1,k}^2\} \varepsilon_t^2 \\
&\quad + 2 \|\hat{\beta}_k - \beta_k\|^2 \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \left(1 + \frac{1}{k}\right)^{-2j} \|\mathbf{X}_{t-j-2}^k\|^2 \varepsilon_t^2
\end{aligned}$$

is $O_P(a_k^{2+\epsilon} \tilde{a}_T^2)$ for all $\epsilon > 0$ since, (i.i), $\sum_{t=k+2}^T \sum_{j=0}^{t-k-2} (1 + \frac{1}{k})^{-2j} \varepsilon_{t-j-1}^2 \varepsilon_t^2 = O_P(a_k^{2+\epsilon} \tilde{a}_T^2)$ for all $\epsilon > 0$, as

$$\begin{aligned}
&\mathbb{E} \left(\sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \left(1 + \frac{1}{k}\right)^{-2j} \varepsilon_{t-j-1}^2 \varepsilon_t^2 \mathbb{I}_{\{|\varepsilon_{t-j-1} \varepsilon_t| \leq \tilde{a}_T\}} \right) \\
&\leq T \mathbb{E}(\varepsilon_1^2 \varepsilon_2^2 \mathbb{I}_{\{|\varepsilon_1 \varepsilon_2| \leq \tilde{a}_T\}}) \sum_{j=0}^{\infty} \left(1 + \frac{1}{k}\right)^{-2j} = O(k \tilde{a}_T^2), \\
&\mathbb{E} \left(\sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \left(1 + \frac{1}{k}\right)^{-2j} \varepsilon_{t-j-1}^2 \varepsilon_t^2 \mathbb{I}_{\{|\varepsilon_{t-j-1} \varepsilon_t| > \tilde{a}_T\}} \right)^{\frac{\eta}{2}} \\
&\leq T \mathbb{E}(|\varepsilon_1 \varepsilon_2|^{\eta} \mathbb{I}_{\{|\varepsilon_1 \varepsilon_2| > \tilde{a}_T\}}) \sum_{j=0}^{\infty} \left(1 + \frac{1}{k}\right)^{-j\eta} = O(k \tilde{a}_T^{\eta})
\end{aligned}$$

by KT for all $\eta \in (0, \alpha)$, (i.ii), similarly,

$$\sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \left(1 + \frac{1}{k}\right)^{-2j} \|\mathbf{X}_{t-j-2}^k\|^2 \varepsilon_t^2 = O_P(a_k^{4+\epsilon} \tilde{a}_T^2)$$

for all $\epsilon > 0$, and is multiplied by $\|\hat{\beta}_k - \beta_k\|^2 = O_P(a_k^2 a_T^{\epsilon-2}) = O_P(a_k^{-2})$ for sufficiently small $\epsilon > 0$ by (10) and $k^3/T \rightarrow 0$, (i.iii),

$$\sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \left(1 + \frac{1}{k}\right)^{-2j} \rho_{t-j-1,k}^2 \varepsilon_t^2 = o_P(\tilde{a}_T^2)$$

since, for $\eta \in [\delta, \alpha)$,

$$\mathbb{E} \left(\sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \left(1 + \frac{1}{k}\right)^{-2j} \rho_{t-j-1,k}^2 \varepsilon_t^2 \right)^{\frac{\eta}{2}} \leq$$

$$\leq T \mathbb{E} |\varepsilon_1|^\eta \mathbb{E} |\rho_{k+1,k}|^\eta \sum_{j=0}^{\infty} \left(1 + \frac{1}{k}\right)^{-j\eta} = O(kT) \mathbb{E} |\rho_{k+1,k}|^\eta$$

is $O_P(kT a_T^{-\eta})$ as $\mathbb{E} |\rho_{k+1,k}|^\eta$ was evaluated in the discussion of σ_{21}^* and $k^2/T \rightarrow 0$, and (ii),

$$\begin{aligned} & \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \sum_{i=0}^{(k-1)\wedge j} b_{j-i,k}^2 e^{tj} \\ & \leq 2 \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \sum_{i=0}^{(k-1)\wedge j} b_{j-i,k}^2 \{\varepsilon_{t-j-1}^2 + \rho_{t-j-1,k}^2\} \varepsilon_t^2 \\ & \quad + 2 \|\hat{\beta}_k - \beta_k\|^2 \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \sum_{i=0}^{(k-1)\wedge j} b_{j-i,k}^2 \|\mathbf{X}_{t-j-2}^k\|^2 \varepsilon_t^2 \\ & = O_P(kT^{-1} \tilde{a}_T^{4+\epsilon} + \|\hat{\beta}_k - \beta_k\|^2 a_k^2 kT^{-1} \tilde{a}_T^{4+\epsilon}) \left(\sum_{i=k+1}^{\infty} |\beta_i| \right)^2 = O_P(a_T^2) \end{aligned}$$

for all $\epsilon > 0$, by taking expectations as in (i) and using $\sum_{j=0}^{t-k-2} \sum_{i=0}^{k-1} b_{j-i,k}^2 \leq k \sum_{j=0}^{t-k-2} b_{jk}^2 \leq k(\sum_{j=0}^{\infty} b_{jk})^2 \leq Ck(\sum_{i=k+1}^{\infty} |\beta_i|)^2$, (10) and the conditions $k^3/T \rightarrow 0$ and $a_T \sum_{i=k+1}^{\infty} |\beta_i| \rightarrow 0$; for example,

$$\begin{aligned} & \mathbb{E} \left(\sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \sum_{i=0}^{k-1} b_{j-i,k}^2 \varepsilon_{t-j-1}^2 \varepsilon_t^2 \mathbb{I}_{\{|\varepsilon_{t-j-1} \varepsilon_t| \leq \tilde{a}_T\}} \right) \\ & \leq T \mathbb{E} (\varepsilon_1^2 \varepsilon_2^2 \mathbb{I}_{\{|\varepsilon_1 \varepsilon_2| \leq \tilde{a}_T\}}) \sum_{j=0}^{T-k-2} \sum_{i=0}^{k-1} b_{j-i,k}^2 = O(k \tilde{a}_T^2) \left(\sum_{i=k+1}^{\infty} |\beta_i| \right)^2 \end{aligned}$$

and, by Hölder's inequality for $\eta \in (0, \alpha)$,

$$\begin{aligned} & \mathbb{E} \left(\sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \sum_{i=0}^{k-1} b_{j-i,k}^2 \varepsilon_{t-j-1}^2 \varepsilon_t^2 \mathbb{I}_{\{|\varepsilon_{t-j-1} \varepsilon_t| > \tilde{a}_T\}} \right)^\eta \\ & \leq T \mathbb{E} (|\varepsilon_1 \varepsilon_2|^\eta \mathbb{I}_{\{|\varepsilon_1 \varepsilon_2| > \tilde{a}_T\}}) \times \sum_{j=0}^{T-k-2} \left(\sum_{i=0}^{k-1} b_{j-i,k}^2 \right)^\eta \\ & \leq O(\tilde{a}_T^\eta) T^{1-\frac{\eta}{2}} \left(\sum_{j=0}^{T-k-2} \sum_{i=0}^{k-1} b_{j-i,k}^2 \right)^\eta = \{O(kT^{\frac{2}{\eta}-1} \tilde{a}_T^2) \left(\sum_{i=k+1}^{\infty} |\beta_i| \right)^2\}^\eta. \end{aligned}$$

By combining (i), (ii) and (10), for all $\epsilon > 0$,

$$\sigma_{31} = O_P(k a_k^{2+\epsilon} \tilde{a}_T^2) (\|\hat{\beta}_k - \beta_k\|_1^2 + \left(\sum_{j=k}^{\infty} |\beta_j| \right)^2) + 2 \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \sum_{i=0}^{k-1} b_{j-i,k}^2 e^{tj}$$

is $O_P(k^2 a_k^4 a_T^\epsilon) + O_P(\tilde{a}_T^2) = O_P(\tilde{a}_T^2)$ since $k^4/T \rightarrow 0$ and $a_T \sum_{i=k+1}^{\infty} |\beta_i| \rightarrow 0$.

Second,

$$\sigma_{32} \leq \|\hat{\beta}_k - \beta_k\|^2 \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\gamma_{j:k}\|^2 \|\mathbf{X}_{t-j-2}^k\|^2 \varepsilon_t^2 = \|\hat{\beta}_k - \beta_k\|^2 O_P(a_k^{4+\epsilon} \tilde{a}_T^2)$$

is $O_P(a_k^6 a_T^\epsilon) = o_P(\tilde{a}_T^2)$ using (10) and $k^4/T \rightarrow 0$, again by taking expectations and replacing the geometric series in powers of $1 + \frac{1}{k}$ by

$$\sum_{j=0}^{T-k-2} \|\gamma_{j:k}\|^2 \leq k \sum_{j=0}^{\infty} \gamma_j^2 = O(k), \quad \sum_{j=0}^{T-k-2} \|\gamma_{j:k}\|^\eta \leq k \sum_{j=0}^{\infty} |\gamma_j|^\eta = O(k)$$

for $\eta \geq \delta$. Third, $\sigma_{33} := \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\gamma_{j:k}\|^2 \rho_{t-j-1,k}^2 \varepsilon_t^2 = o_P(\tilde{a}_T^2)$, similarly to σ_{21}^* .

Returning to the initial decomposition of $\mathbf{E}^\dagger \|\sigma_3\|^2$, we can conclude that $\mathbf{E}^\dagger \|\sigma_3\|^2 = o_P(\tilde{a}_T^2)$ for $k^4/T \rightarrow 0$. By combining it with the evaluations of σ_2^* and σ_2^\dagger , we complete the proof of part (b) for π equal to the identity.

For an r.p. π , we start from

$$\sigma_1 + \sigma_2^* = \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \hat{\gamma}_{j:k} \hat{\varepsilon}_{\pi(t-j-1)} (\hat{\varepsilon}_{\pi(t)} - \varepsilon_{\pi(t)}) w_{t-j-1} w_t.$$

If w_t are Rademacher, then

$$\begin{aligned} \mathbf{E}^\dagger \|\sigma_1 + \sigma_2^*\|^2 &= \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\hat{\gamma}_{j:k}\|^2 \mathbf{E}^\dagger \{\hat{\varepsilon}_{\pi(t-j-1)}^2 (\hat{\varepsilon}_{\pi(t)} - \varepsilon_{\pi(t)})^2\} \\ &= \mathbf{E}^\dagger \{\hat{\varepsilon}_{\pi(k+1)}^2 (\hat{\varepsilon}_{\pi(k+2)} - \varepsilon_{\pi(k+2)})^2\} \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\hat{\gamma}_{j:k}\|^2, \end{aligned}$$

with $\mathbf{E}^\dagger \{\hat{\varepsilon}_{\pi(k+1)}^2 (\hat{\varepsilon}_{\pi(k+2)} - \varepsilon_{\pi(k+2)})^2\} \leq O(T^{-2}) \hat{\sigma}_{T,k}^2 \|\hat{\varepsilon}_T - \varepsilon_T\|^2 = O_P(T^{\epsilon-2} a_k^2 a_T^2)$, so

$$\begin{aligned} \mathbf{E}^\dagger \|\sigma_1 + \sigma_2^*\|^2 &= O_P(T^{\epsilon-1} a_k^2 a_T^2) \sum_{j=0}^{T-k-2} \|\hat{\gamma}_{j:k}\|^2 \\ &= O_P(T^{\epsilon-1} k a_k^2 a_T^2) (\|\gamma\|^2 + \|\hat{\gamma}_{T+k-2} - \gamma_{T+k-2}\|^2) \end{aligned}$$

is $O_P(T^{\epsilon-1} k a_k^2 a_T^2)$ for all $\epsilon > 0$, using equation (A.1.16) and (10). On the other hand, if $w_t = 1$ P^\dagger -a.s. (all t), then

$$\begin{aligned} \mathbf{E}^\dagger \|\sigma_1 + \sigma_2^*\|^2 &= \sum_{s,t=k+2}^T \sum_{i=0}^{s-k-2} \sum_{j=0}^{t-k-2} \hat{\gamma}'_{i:k} \hat{\gamma}_{j:k} \times \\ &\times \mathbf{E}^\dagger \{\hat{\varepsilon}_{\pi(s-i-1)} \hat{\varepsilon}_{\pi(t-j-1)} (\hat{\varepsilon}_{\pi(s)} - \varepsilon_{\pi(s)}) (\hat{\varepsilon}_{\pi(t)} - \varepsilon_{\pi(t)})\} \\ &= \mathbf{E}^\dagger \{\hat{\varepsilon}_{\pi(k+1)}^2 (\hat{\varepsilon}_{\pi(k+2)} - \varepsilon_{\pi(k+2)})^2\} \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\hat{\gamma}_{j:k}\|^2 \\ &+ \mathbf{E}^\dagger \{\hat{\varepsilon}_{\pi(k+1)} \hat{\varepsilon}_{\pi(k+2)} (\hat{\varepsilon}_{\pi(T)} - \varepsilon_{\pi(T)})^2\} \sum_{t=k+2}^T \sum_{i,j=0}^{t-k-2} \mathbb{I}_{\{i \neq j\}} \hat{\gamma}'_{i:k} \hat{\gamma}_{j:k} \\ &+ \mathbf{E}^\dagger \{\hat{\varepsilon}_{\pi(k+1)}^2 (\hat{\varepsilon}_{\pi(k+2)} - \varepsilon_{\pi(k+2)}) (\hat{\varepsilon}_{\pi(T)} - \varepsilon_{\pi(T)})\} \\ &\times \sum_{s,t=k+2}^T \sum_{i=\max\{0,s-t\}}^{s-k-2} \hat{\gamma}'_{i:k} \hat{\gamma}_{t-s+i:k} \mathbb{I}_{\#\{s,t,s-i-1\}=3} \\ &+ \mathbf{E}^\dagger \{\hat{\varepsilon}_{\pi(k+1)} \hat{\varepsilon}_{\pi(k+2)} (\hat{\varepsilon}_{\pi(k+3)} - \varepsilon_{\pi(k+3)}) (\hat{\varepsilon}_{\pi(T)} - \varepsilon_{\pi(T)})\} \\ &\times \sum_{s,t=k+2}^T \sum_{i=0}^{s-k-2} \sum_{j=0}^{t-k-2} \mathbb{I}_{\#\{s-i-1,t-j-1,s,t\}=4} \hat{\gamma}'_{i:k} \hat{\gamma}_{j:k} \end{aligned}$$

by separating according to the possible subscript repetitions. Here, first, $\mathbf{E}^\dagger\{\hat{\varepsilon}_{\pi(k+1)}^2(\hat{\varepsilon}_{\pi(k+2)} - \varepsilon_{\pi(k+2)})^2\} = O_P(T^{\epsilon-2}a_k^2a_T^2)$ for all $\epsilon > 0$, as found earlier. Second,

$$\begin{aligned} \mathbf{E}^\dagger\{\hat{\varepsilon}_{\pi(k+1)}\hat{\varepsilon}_{\pi(k+2)}(\hat{\varepsilon}_{\pi(T)} - \varepsilon_{\pi(T)})^2\} &= O(T^{-3}) \sum_{u,v,s=k+1}^T \mathbb{I}_{\#\{u,v,s\}=3} \hat{\varepsilon}_u \hat{\varepsilon}_v (\hat{\varepsilon}_s - \varepsilon_s)^2 \\ &\leq O(T^{-3}) \left\{ \left(\sum_{u=k+1}^T \hat{\varepsilon}_u \right)^2 \|\hat{\boldsymbol{\varepsilon}}_T - \boldsymbol{\varepsilon}_T\|^2 - 2 \left(\sum_{u=k+1}^T \hat{\varepsilon}_u \right) \sum_{s=k+1}^T \hat{\varepsilon}_s (\hat{\varepsilon}_s - \varepsilon_s)^2 \right. \\ &\quad \left. + \sum_{u=k+1}^T \hat{\varepsilon}_u^2 (\hat{\varepsilon}_u - \varepsilon_u)^2 \right\} \\ &\leq O(T^{-3}) \left\{ \left(\sum_{u=k+1}^T \hat{\varepsilon}_u \right)^2 + 2\hat{\sigma}_{Tk} \left| \sum_{u=k+1}^T \hat{\varepsilon}_u \right| + \hat{\sigma}_{Tk}^2 \right\} \|\hat{\boldsymbol{\varepsilon}}_T - \boldsymbol{\varepsilon}_T\|^2 \end{aligned}$$

Hence, using $\sum_{t=k+1}^T \varepsilon_t = O_P(a_T l_T)$, equation (A.1.14) and $k^3/T \rightarrow 0$,

$$\begin{aligned} \mathbf{E}^\dagger\{\hat{\varepsilon}_{\pi(k+1)}\hat{\varepsilon}_{\pi(k+2)}(\hat{\varepsilon}_{\pi(T)} - \varepsilon_{\pi(T)})^2\} &= O_P(T^{-3}) \{a_T^2 l_T + k a_k^2 T^\epsilon + k^{1/2} a_k a_T T^\epsilon\} \\ &\quad \times \|\hat{\boldsymbol{\varepsilon}}_T - \boldsymbol{\varepsilon}_T\|^2 = O_P(T^{-3} a_T^2 l_T) \|\hat{\boldsymbol{\varepsilon}}_T - \boldsymbol{\varepsilon}_T\|^2 = O_P(T^{\epsilon-3} a_k^2 a_T^2) \end{aligned}$$

for all $\epsilon > 0$. Third, with $|\sum_{u=k+1}^T \hat{\varepsilon}_u^2 (\hat{\varepsilon}_u - \varepsilon_u)| \leq \hat{\sigma}_{Tk}^2 \|\hat{\boldsymbol{\varepsilon}}_T - \boldsymbol{\varepsilon}_T\|$, we find

$$\begin{aligned} &\mathbf{E}^\dagger\{\hat{\varepsilon}_{\pi(k+1)}^2(\hat{\varepsilon}_{\pi(k+2)} - \varepsilon_{\pi(k+2)})(\hat{\varepsilon}_{\pi(T)} - \varepsilon_{\pi(T)})\} \\ &= O(T^{-3}) \sum_{u,v,s=k+1}^T \mathbb{I}_{\#\{u,v,s\}=3} \hat{\varepsilon}_u^2 (\hat{\varepsilon}_v - \varepsilon_v) (\hat{\varepsilon}_s - \varepsilon_s) \\ &\leq O(T^{-3}) [\hat{\sigma}_{Tk}^2 \left\{ \sum_{v=k+1}^T (\hat{\varepsilon}_v - \varepsilon_v) \right\}^2 \\ &\quad - 2 \sum_{u=k+1}^T \hat{\varepsilon}_u^2 (\hat{\varepsilon}_u - \varepsilon_u) \sum_{u=k+1}^T (\hat{\varepsilon}_u - \varepsilon_u) + \sum_{u=k+1}^T \hat{\varepsilon}_u^2 (\hat{\varepsilon}_u - \varepsilon_u)^2] \\ &= O_P(T^{\epsilon-3} k a_k^2 a_T^2 + T^{\epsilon-3} k^{1/2} a_k a_T^2 \|\hat{\boldsymbol{\varepsilon}}_T - \boldsymbol{\varepsilon}_T\| + T^{-3} \hat{\sigma}_{Tk}^2 \|\hat{\boldsymbol{\varepsilon}}_T - \boldsymbol{\varepsilon}_T\|^2) \\ &= O_P(T^{\epsilon-3} k a_k^2 a_T^2 + T^{\epsilon-3} k^{1/2} a_k^2 a_T + T^{\epsilon-3} a_k^2) = O_P(T^{\epsilon-3} k a_k^2 a_T^2) \end{aligned}$$

for all $\epsilon > 0$. Fourth,

$$\begin{aligned} &\mathbf{E}^\dagger\{\hat{\varepsilon}_{\pi(k+1)}\hat{\varepsilon}_{\pi(k+2)}(\hat{\varepsilon}_{\pi(k+3)} - \varepsilon_{\pi(k+3)})(\hat{\varepsilon}_{\pi(T)} - \varepsilon_{\pi(T)})\} \\ &= O(T^{-4}) \sum_{u,v,s,t=k+1}^T \mathbb{I}_{\#\{u,v,s,t\}=4} \hat{\varepsilon}_u \hat{\varepsilon}_t (\hat{\varepsilon}_v - \varepsilon_v) (\hat{\varepsilon}_s - \varepsilon_s) \\ &= O(T^{-4}) \left\{ \sum_{u,v=k+1}^T \mathbb{I}_{u \neq v} \hat{\varepsilon}_u (\hat{\varepsilon}_v - \varepsilon_v) \right\}^2 - \sum_{u,v,s=k+1}^T \mathbb{I}_{\#\{u,v,s\}=3} \hat{\varepsilon}_u \hat{\varepsilon}_v (\hat{\varepsilon}_s - \varepsilon_s)^2 \\ &\quad - \sum_{u,v,s=k+1}^T \mathbb{I}_{\#\{u,v,s\}=3} \hat{\varepsilon}_u^2 (\hat{\varepsilon}_v - \varepsilon_v) (\hat{\varepsilon}_s - \varepsilon_s) - \sum_{u,v=k+1}^T \mathbb{I}_{u \neq v} \hat{\varepsilon}_u^2 (\hat{\varepsilon}_v - \varepsilon_v)^2 \}, \end{aligned}$$

where the magnitude order of the last three sums was determined above, so

$$\begin{aligned}
&= O(T^{-4})\left\{\sum_{u=k+1}^T \hat{\varepsilon}_u \sum_{v=k+1}^T (\hat{\varepsilon}_v - \varepsilon_v) - \sum_{u=k+1}^T \hat{\varepsilon}_u (\hat{\varepsilon}_u - \varepsilon_u)\right\}^2 + O_P(T^{\epsilon-4} k a_k^2 a_T^2) \\
&\leq O(T^{-4})\left[\left(\sum_{u=k+1}^T \hat{\varepsilon}_u\right)^2 \left\{\sum_{v=k+1}^T (\hat{\varepsilon}_v - \varepsilon_v)\right\}^2 + \hat{\sigma}_{T,k}^2 \|\hat{\varepsilon}_T - \varepsilon_T\|^2\right] + O_P(T^{\epsilon-4} k a_k^2 a_T^2) \\
&= O_P(T^{-4} (a_T^2 l_T + k a_k^2 T^\epsilon) k a_k^2 T^\epsilon) + O_P(T^{\epsilon-4} k a_k^2 a_T^2) = O_P(T^{\epsilon-4} k a_k^2 a_T^2)
\end{aligned}$$

for all $\epsilon > 0$ if $k^3/T \rightarrow 0$. Returning to $\|\sigma_1 + \sigma_2^*\|$,

$$\begin{aligned}
\mathbb{E}^\dagger \|\sigma_1 + \sigma_2^*\|^2 &= O_P(T^{\epsilon-1} a_k^2 a_T^2) \sum_{j=0}^{T-k-2} \|\hat{\gamma}_{j:k}\|^2 \\
&\quad + O_P(T^{\epsilon-3} k a_k^2 a_T^2) \sum_{t=k+2}^T \sum_{i,j=0}^{t-k-2} \mathbb{I}_{\{i \neq j\}} \hat{\gamma}'_{i:k} \hat{\gamma}_{j:k} \\
&\quad + O_P(T^{\epsilon-3} k a_k^2 a_T^2) \sum_{s,t=k+2}^T \sum_{i=\max\{0,s-t\}}^{s-k-2} \hat{\gamma}'_{i:k} \hat{\gamma}_{t-s+i:k} \mathbb{I}_{\#\{s,t,s-i-1\}=3} \\
&\quad + O_P(T^{\epsilon-4} k a_k^2 a_T^2) \sum_{s,t=k+2}^T \sum_{i=0}^{s-k-2} \sum_{j=0}^{t-k-2} \mathbb{I}_{\#\{s-i-1,t-j-1,s,t\}=4} \hat{\gamma}'_{i:k} \hat{\gamma}_{j:k} \\
&= O_P(T^{\epsilon-1} k a_k^2 a_T^2) \|\hat{\gamma}\|^2 + O_P(T^{\epsilon-2} k^2 a_k^2 a_T^2) \|\hat{\gamma}\|_1^2 \\
&\quad + O_P(T^{\epsilon-2} k^3 a_k^2 a_T^2 + T^{\epsilon-1} k^2 a_k^2 a_T) + O_P(T^{\epsilon-2} k^3 a_k^2 a_T^2) \|\hat{\gamma}\|_1^2
\end{aligned}$$

is $O_P(T^{\epsilon-1} k a_k^2 a_T^2)$ for all $\epsilon > 0$ if $k^3/T \rightarrow 0$, the magnitude orders using (A.1.25), (A.1.27) and reasoning applied previously. Hence, $\|\sigma_1 + \sigma_2^*\| = O_{P^\dagger}(T^{\epsilon-1/2} k^{1/2} a_k a_T)$ in P -probability for all $\epsilon > 0$ and an r.p. π .

Next, with $\varpi_{kj} := \sum_{m=k+1}^j \beta_m \gamma_{j-m}$ ($j = k+1, \dots, T-k-2$), σ_2^\dagger can be written as

$$\begin{aligned}
\sigma_2^\dagger &= \sum_{t=2k+2}^T \left[\sum_{i=1}^{t-k-1} \gamma_{i-1:k} \varepsilon_{t-i}^\dagger \right] \left[\sum_{j=k+1}^{t-k-1} \varpi_{kj} \varepsilon_{t-j}^\dagger \right] \\
&= \sum_{t=2k+2}^T \sum_{i=k+1}^{t-k-1} \gamma_{i-1:k} \varpi_{ki} \varepsilon_{\pi(t-i)}^2 + \sum_{t=2k+2}^T \sum_{i=1}^{t-k-1} \sum_{j=k+1}^{t-k-1} \mathbb{I}_{i \neq j} \gamma_{i-1:k} \varpi_{kj} \varepsilon_{t-i}^\dagger \varepsilon_{t-j}^\dagger,
\end{aligned}$$

where, independently of how w_t are specified,

$$\begin{aligned}
\mathbb{E}^\dagger \left\| \sum_{t=2k+2}^T \sum_{i=k+1}^{t-k-1} \gamma_{i-1:k} \varpi_{ki} \varepsilon_{\pi(t-i)}^2 \right\| &\leq \mathbb{E}^\dagger \{\varepsilon_{\pi(T)}^2\} \sum_{t=2k+2}^T \sum_{i=k+1}^{t-k-1} \|\gamma_{i-1:k}\| \|\varpi_{ki}\| \\
&= \sigma_T^2 \|\gamma\|_1^2 \sum_{m=k+1}^{\infty} |\beta_m| = o_P(a_T)
\end{aligned}$$

under Assumption 1(b) and the condition $\sum_{m=k+1}^{\infty} |\beta_m| = o(a_T^{-1})$. Further, with $f_{s,t} := \sum_{j=1+\max\{k,s-t\}}^{T-t} \gamma_{j+t-s-1:k} \varpi_{kj}$, the term

$$\sigma_{2 \times}^\dagger := \sum_{t=2k+2}^T \sum_{i=1}^{t-k-1} \sum_{j=k+1}^{t-k-1} \mathbb{I}_{i \neq j} \gamma_{i-1:k} \varpi_{kj} \varepsilon_{t-i}^\dagger \varepsilon_{t-j}^\dagger = \sum_{s=2k+1}^{T-1} \sum_{t=k+1}^{T-k-1} \mathbb{I}_{s \neq t} \varepsilon_s^\dagger \varepsilon_t^\dagger f_{s,t}$$

has, for Rademacher w_t ,

$$\mathbf{E}^\dagger \|\sigma_{2 \times}^\dagger\|^2 = \mathbf{E}^\dagger (\varepsilon_{\pi(k+1)}^2 \varepsilon_{\pi(k+2)}^2) \left(\sum_{s=2k+1}^{T-1} \sum_{t=k+1}^{T-k-1} \mathbb{I}_{s \neq t} \|f_{s,t}\|^2 + \sum_{s,t=2k+1}^{T-k-1} f'_{s,t} f_{t,s} \right) := \mathbf{e}_{2 \times}^\dagger,$$

where

$$\begin{aligned} \sum_{s=2k+1}^{T-1} \sum_{t=k+1}^{T-k-1} \mathbb{I}_{s \neq t} \|f_{s,t}\|^2 &\leq \|\gamma\|^2 \sum_{s=2k+1}^{T-1} \sum_{t=k+1}^{T-k-1} \mathbb{I}_{s \neq t} \left(\sum_{j=1+\max\{k,s-t\}}^{T-t} |\varpi_{kj}| \right)^2 \\ &\leq T^2 \|\gamma\|^2 \left(\sum_{j=k+1}^{T-k-1} \sum_{m=k+1}^j |\beta_m| |\gamma_{j-m}| \right)^2 \\ &\leq T^2 \|\gamma\|_1^4 \left(\sum_{m=k+1}^{\infty} |\beta_m| \right)^2 = o(T^2 a_T^{-2}), \end{aligned}$$

and similarly, also $\sum_{s,t=2k+1}^{T-k-1} f'_{s,t} f_{t,s} = o(T^2 a_T^{-2})$, so

$$\mathbf{E}^\dagger \|\sigma_{2 \times}^\dagger\|^2 = \mathbf{e}_{2 \times}^\dagger = o(T^2 a_T^{-2}) \mathbf{E}^\dagger (\varepsilon_{\pi(k+1)}^2 \varepsilon_{\pi(k+2)}^2) = o_P(a_T^2)$$

using equation (A.1.18). On the other hand, for $w_t = 1$ a.s. (all t),

$$\begin{aligned} \mathbf{E}^\dagger \|\sigma_{2 \times}^\dagger\|^2 &= \mathbf{e}_{2 \times}^\dagger + \mathbf{E}^\dagger (\varepsilon_{\pi(k+1)}^2 \varepsilon_{\pi(k+2)}^2 \varepsilon_{\pi(T)}) \\ &\times \left(\sum_{s=2k+1}^{T-1} \sum_{t,u=k+1}^{T-k-1} \mathbb{I}_{\#\{u,s,t\}=3} f'_{st} f_{su} + \sum_{s=2k+1}^{T-k-1} \sum_{t=k+1}^{T-k-1} \sum_{u=2k+1}^{T-1} \mathbb{I}_{\#\{u,s,t\}=3} f'_{st} f_{us} \right. \\ &+ \sum_{s=2k+1}^{T-1} \sum_{t=2k+1}^{T-k-1} \sum_{u=k+1}^{T-k-1} \mathbb{I}_{\#\{u,s,t\}=3} f'_{st} f_{tu} + \sum_{s,u=2k+1}^{T-1} \sum_{t=k+1}^{T-k-1} \mathbb{I}_{\#\{u,s,t\}=3} f'_{st} f_{ut} \left. \right) \\ &+ \mathbf{E}^\dagger (\varepsilon_{\pi(k+1)} \varepsilon_{\pi(k+2)} \varepsilon_{\pi(T-1)} \varepsilon_{\pi(T)}) \sum_{s,u=2k+1}^{T-1} \sum_{t,v=k+1}^{T-k-1} \mathbb{I}_{\#\{u,v,s,t\}=4} f'_{st} f_{uv} \end{aligned}$$

is $o_P(a_T^2)$ as

$$\begin{aligned} &\left| \sum_{s=2k+1}^{T-1} \sum_{t,u=k+1}^{T-k-1} \mathbb{I}_{\#\{u,s,t\}=3} f'_{st} f_{su} \right| \leq \sum_{s=2k+1}^{T-1} \left(\sum_{t=k+1}^{T-k-1} \mathbb{I}_{s \neq t} \|f_{st}\| \right)^2 \\ &\leq \sum_{s=2k+1}^{T-1} \left(\sum_{t=k+1}^{T-k-1} \mathbb{I}_{s \neq t} \sum_{j=1+\max\{k,s-t\}}^{T-t} \|\gamma_{j+t-s-1:k}\| |\varpi_{kj}| \right)^2 \\ &\leq T^3 \|\gamma\|^2 \left(\sum_{j=k+1}^{T-k-1} \sum_{m=k+1}^j |\beta_m| |\gamma_{j-m}| \right)^2 \leq T^3 \|\gamma\|_1^4 \left(\sum_{j=k+1}^{\infty} |\beta_j| \right)^2 = o(T^3 a_T^{-2}), \end{aligned}$$

and similarly

$$\sum_{s=2k+1}^{T-k-1} \sum_{t=k+1}^{T-k-1} \sum_{u=2k+1}^{T-1} \mathbb{I}_{\#\{u,s,t\}=3} f'_{st} f_{us} = o(T^3 a_T^{-2}),$$

also

$$\sum_{s=2k+1}^{T-1} \sum_{t=2k+1}^{T-k-1} \sum_{u=k+1}^{T-k-1} \mathbb{I}_{\#\{u,s,t\}=3} f'_{st} f_{tu} = o(T^3 a_T^{-2}),$$

and eventually, likewise,

$$\sum_{s,u=2k+1}^{T-1} \sum_{t=k+1}^{T-k-1} \mathbb{I}_{\#\{u,s,t\}=3} f'_{st} f_{ut} = o(T^3 a_T^{-2}),$$

whereas

$$\begin{aligned} & \left| \sum_{s,u=2k+1}^{T-1} \sum_{t,v=k+1}^{T-k-1} \mathbb{I}_{\#\{u,v,s,t\}=4} f'_{st} f_{uv} \right| \leq \left(\sum_{s=2k+1}^{T-1} \sum_{t=k+1}^{T-k-1} \mathbb{I}_{s \neq t} \|f_{st}\| \right)^2 \\ & \leq T^4 \|\gamma\|^2 \left(\sum_{j=k+1}^{T-k-1} \sum_{m=k+1}^j |\beta_m| |\gamma_{j-m}| \right)^2 = o(T^4 a_T^{-2}) \end{aligned}$$

and the expectations were evaluated in (A.1.19) and (A.1.20). By combining the above results with Markov's inequality, it follows that $\sigma_2^\dagger = o_{P^\dagger}(a_T)$ in P -probability.

Finally, we consider σ_3 , still in the case where π is an r.p.:

$$\begin{aligned} \|\sigma_3\| & \leq \left\| \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} (\hat{\gamma}_{j:k} - \gamma_{j:k}) \hat{\varepsilon}_{\pi(t-j-1)} \varepsilon_{\pi(t)} w_{t-j-1} w_t \right\| \\ & \quad + \left\| \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \gamma_{j:k} (\hat{\varepsilon}_{\pi(t-j-1)} - \varepsilon_{\pi(t-j-1)}) \varepsilon_{\pi(t)} w_{t-j-1} w_t \right\|, \end{aligned}$$

where the second norm on the right-hand side is of the same form as $\|\sigma_1 + \sigma_2^*\|$, with $\gamma_{j:k}$ in place of $\hat{\gamma}_{j:k}$, and is $o_{P^\dagger}(T^{\epsilon-1/2} k^{1/2} a_k a_T)$ in P -probability, for all $\epsilon > 0$, by a similar argument as for $\sigma_1 + \sigma_2^*$. Regarding the other norm, say $\|\sigma_{31}\|$, for Rademacher $\{w_t\}$ it holds that

$$\begin{aligned} \mathbb{E}^\dagger \|\sigma_{31}\|^2 & = \mathbb{E}^\dagger \{ \hat{\varepsilon}_{\pi(k+1)}^2 \varepsilon_{\pi(k+2)}^2 \} \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\hat{\gamma}_{j:k} - \gamma_{j:k}\|^2 \\ & \leq O(T^{-1} k) \sigma_T^2 \hat{\sigma}_{T_k}^2 \|\hat{\gamma}_{T+k-2} - \gamma_{T+k-2}\|^2 \\ & = O(T^{-1} k a_T^4) \|\hat{\beta}_k - \beta_k\|^2 = O_P(T^{\epsilon-1} k a_k^2 a_T^2) \end{aligned}$$

using equations (A.1.25), (A.1.16) and (10), for all $\epsilon > 0$. Similarly, for $w_t = 1$ P^\dagger -a.s. (all t),

$$\begin{aligned} \mathbb{E}^\dagger \sigma_{31} & = \sum_{s,t=k+2}^T \sum_{i=0}^{s-k-2} \sum_{j=0}^{t-k-2} (\hat{\gamma}_{i:k} - \gamma_{i:k})' (\hat{\gamma}_{j:k} - \gamma_{j:k}) \\ & \quad \times \mathbb{E}^\dagger \{ \hat{\varepsilon}_{\pi(s-i-1)} \hat{\varepsilon}_{\pi(t-j-1)} \varepsilon_{\pi(s)} \varepsilon_{\pi(t)} \} \\ & = \mathbb{E}^\dagger \{ \hat{\varepsilon}_{\pi(k+1)}^2 \varepsilon_{\pi(k+2)}^2 \} \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\hat{\gamma}_{j:k} - \gamma_{j:k}\|^2 \end{aligned}$$

$$\begin{aligned}
& + \mathbb{E}^\dagger \{ \hat{\varepsilon}_{\pi(k+1)} \hat{\varepsilon}_{\pi(k+2)} \varepsilon_{\pi(T)}^2 \} \sum_{t=k+2}^T \sum_{i,j=0}^{t-k-2} \mathbb{I}_{\{i \neq j\}} (\hat{\gamma}_{i:k} - \gamma_{i:k})' (\hat{\gamma}_{j:k} - \gamma_{j:k}) \\
& + \mathbb{E}^\dagger \{ \hat{\varepsilon}_{\pi(k+1)}^2 \varepsilon_{\pi(k+2)} \varepsilon_{\pi(T)} \} \\
& \times \sum_{s,t=k+2}^T \sum_{i=\max\{0,s-t\}}^{s-k-2} (\hat{\gamma}_{i:k} - \gamma_{i:k})' (\hat{\gamma}_{t-s+i:k} - \gamma_{t-s+i:k}) \mathbb{I}_{\#\{s,t,s-i-1\}=3} \\
& + \mathbb{E}^\dagger \{ \hat{\varepsilon}_{\pi(k+1)} \hat{\varepsilon}_{\pi(k+2)} \varepsilon_{\pi(k+3)} \varepsilon_{\pi(T)} \} \\
& \times \sum_{s,t=k+2}^T \sum_{i=0}^{s-k-2} \sum_{j=0}^{t-k-2} \mathbb{I}_{\#\{s-i-1,t-j-1,s,t\}=4} (\hat{\gamma}_{i:k} - \gamma_{i:k})' (\hat{\gamma}_{j:k} - \gamma_{j:k})
\end{aligned}$$

implying that

$$\begin{aligned}
\mathbb{E}^\dagger \sigma_{31} & = O_P(T^{\epsilon-1} k a_k^2 a_T^2) + O_P(T^{-2} k^2 a_T^4 l_T) \|\hat{\gamma}_{T+k-2} - \gamma_{T+k-2}\|^2 \\
& \quad + O_P(T^{-2} k^3 a_k a_T^{3+\epsilon} l_T + T^{-1} k a_T^3 l_T) \|\hat{\gamma}_{T+k-2} - \gamma_{T+k-2}\| \\
& = O_P(T^{\epsilon-1} k a_k^2 a_T^2) + O_P(T^{-2} k^2 a_T^4 l_T) \|\hat{\beta}_k - \beta_k\|^2 \\
& \quad + O_P(T^{-2} k^3 a_k a_T^{3+\epsilon} l_T + T^{-1} k a_T^3 l_T) \|\hat{\beta}_k - \beta_k\| = O_P(T^{\epsilon-1} k a_k^2 a_T^2),
\end{aligned}$$

for all $\epsilon > 0$, as

$$\begin{aligned}
& \sum_{s,t=k+2}^T \sum_{i=\max\{0,s-t\}}^{s-k-2} \|\hat{\gamma}_{i:k} - \gamma_{i:k}\| \|\hat{\gamma}_{t-s+i:k} - \gamma_{t-s+i:k}\| \mathbb{I}_{\#\{s,t,s-i-1\}=3} \\
& \leq 2T \|\hat{\gamma}_{T+k-2} - \gamma_{T+k-2}\| \sum_{i=0}^{T-k-2} i \|\hat{\gamma}_{i:k} - \gamma_{i:k}\| \\
& = \|\hat{\gamma}_{T+k-2} - \gamma_{T+k-2}\| O_P(k^3 a_k T a_T^{\epsilon-1} + k T^2 a_T^{-1})
\end{aligned}$$

by (A.1.27) and $k^3/T \rightarrow 0$, so $\|\sigma_3\| = o_{P^\dagger}(T^{\epsilon-1/2} k^{1/2} a_k a_T)$ in P -probability.

Combined with the evaluations of $\|\sigma_1 + \sigma_2^*\|$ and σ_2^\dagger , this proves part (b) in the r.p. case.

PROOF OF PART (C) We consider the bootstrap schemes separately for

$$S_{0\epsilon}^{k\dagger} - \sigma_2^\dagger = \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \gamma_{j:k} \varepsilon_{\pi(t-j-1)} \varepsilon_{\pi(t)} w_{t-j-1} w_t,$$

and we use previous evaluations for $\|\sigma_2^\dagger\| = o_{P^\dagger}(a_T)$ in P -probability.

For π equal to the identity it holds that

$$\begin{aligned}
\mathbb{E}^\dagger \|S_{0\epsilon}^{k\dagger} - \sigma_2^\dagger\|^2 & = \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\gamma_{j:k}\|^2 \varepsilon_{t-j-1}^2 \varepsilon_t^2 \\
& = \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\gamma_{j:k}\|^2 \varepsilon_{t-j-1}^2 \varepsilon_t^2 (\mathbb{I}_{|\varepsilon_{t-j-1} \varepsilon_t| \leq \tilde{a}_T} + \mathbb{I}_{|\varepsilon_{t-j-1} \varepsilon_t| > \tilde{a}_T})
\end{aligned}$$

with

$$\mathbb{E} \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\gamma_{j:k}\|^2 \varepsilon_{t-j-1}^2 \varepsilon_t^2 \mathbb{I}_{|\varepsilon_{t-j-1} \varepsilon_t| \leq \tilde{a}_T} \leq T k \mathbb{E}(\varepsilon_1^2 \varepsilon_2^2 \mathbb{I}_{|\varepsilon_1 \varepsilon_2| \leq \tilde{a}_T}) \sum_{j=0}^{\infty} \gamma_j^2,$$

which is $O(\tilde{a}_T^2 k)$, and for $\eta \in [\delta, \alpha)$,

$$\mathbb{E} \left(\sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\gamma_{j:k}\|^2 \varepsilon_{t-j-1}^2 \mathbb{I}_{|\varepsilon_{t-j-1} \varepsilon_t| > \tilde{a}_T} \right)^{\frac{\eta}{2}} \leq T k \mathbb{E} (|\varepsilon_1 \varepsilon_2|^{\eta} \mathbb{I}_{|\varepsilon_1 \varepsilon_2| > \tilde{a}_T}) \sum_{j=0}^{\infty} |\gamma_j|^{\eta}$$

which is $O(\tilde{a}_T^{\eta} k)$ by KT, so

$$\mathbb{E}^{\dagger} \|S_{0\varepsilon}^{k\dagger} - \sigma_2^{\dagger}\|^2 = O_P(\tilde{a}_T^2 k^{2/\eta}) \text{ and } \|S_{0\varepsilon}^{k\dagger} - \sigma_2^{\dagger}\| = o_{P^{\dagger}}(\tilde{a}_T a_k^{1+\epsilon})$$

in P -probability, for $\epsilon > 0$, by Markov's inequality. Adding $\|\sigma_2^{\dagger}\| = o_{P^{\dagger}}(a_T)$ completes the case π equal to the identity.

If π is an r.p., for $S_{0\varepsilon}^{k\dagger}$ it holds that

$$\begin{aligned} \mathbb{E}^{\dagger} \|S_{0\varepsilon}^{k\dagger} - \sigma_2^{\dagger}\| &\leq \mathbb{E}^{\dagger} \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\gamma_{j:k}\| |\varepsilon_{\pi(t-j-1)}| |\varepsilon_{\pi(t)}| \\ &\leq O_P(T^{-1}k) \left(\sum_{t=k+1}^T |\varepsilon_t| \right)^2 = O_P(T^{-1}k \max\{T^2, a_T^2 l_T^2\}). \end{aligned}$$

Hence, by Markov's inequality, $\|S_{0\varepsilon}^{k\dagger} - \sigma_2^{\dagger}\| = O_{P^{\dagger}}(T^{-1}k \max\{T^2, a_T^2 l_T^2\})$ in P -probability. For large α this can be sharpened slightly by evaluating the conditional variance. For Rademacher $\{w_t\}$,

$$\mathbb{E}^{\dagger} \|S_{0\varepsilon}^{k\dagger} - \sigma_2^{\dagger}\|^2 = \mathbb{E}^{\dagger} \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\gamma_{j:k}\|^2 \varepsilon_{\pi(t-j-1)}^2 \varepsilon_{\pi(t)}^2 \leq O_P(T^{-1}k) \sigma_T^4$$

is $O_P(T^{-1}k a_T^4)$, whereas for constant w_t ,

$$\begin{aligned} \mathbb{E}^{\dagger} \|S_{0\varepsilon}^{k\dagger} - \sigma_2^{\dagger}\|^2 &= \sum_{s,t=k+2}^T \sum_{i=0}^{s-k-2} \sum_{j=0}^{t-k-2} \gamma'_{i:k} \gamma_{j:k} \mathbb{E}^{\dagger} \{ \varepsilon_{\pi(s-i-1)} \varepsilon_{\pi(t-j-1)} \varepsilon_{\pi(s)} \varepsilon_{\pi(t)} \} \\ &= \mathbb{E}^{\dagger} \{ \varepsilon_{\pi(k+1)}^2 \varepsilon_{\pi(k+2)}^2 \} \sum_{t=k+2}^T \sum_{j=0}^{t-k-2} \|\gamma_{j:k}\|^2 \\ &\quad + \mathbb{E}^{\dagger} \{ \varepsilon_{\pi(k+1)} \varepsilon_{\pi(k+2)} \varepsilon_{\pi(T)}^2 \} \sum_{t=k+2}^T \sum_{i,j=0}^{t-k-2} \mathbb{I}_{\{i \neq j\}} \gamma'_{i:k} \gamma_{j:k} \\ &\quad + \mathbb{E}^{\dagger} \{ \varepsilon_{\pi(k+1)}^2 \varepsilon_{\pi(k+2)} \varepsilon_{\pi(T)} \} \\ &\quad \times \sum_{s,t=k+2}^T \sum_{i=\max\{0,s-t\}}^{s-k-2} \gamma'_{i:k} \gamma_{t-s+i:k} \mathbb{I}_{\#\{s,t,s-i-1\}=3} \\ &\quad + \mathbb{E}^{\dagger} \{ \varepsilon_{\pi(k+1)} \varepsilon_{\pi(k+2)} \varepsilon_{\pi(k+3)} \varepsilon_{\pi(T)} \} \\ &\quad \times \sum_{s,t=k+2}^T \sum_{i=0}^{s-k-2} \sum_{j=0}^{t-k-2} \mathbb{I}_{\#\{s-i-1,t-j-1,s,t\}=4} \gamma'_{i:k} \gamma_{j:k} \\ &= O_P(T^{-1}k a_T^4) \|\gamma\|^2 + O_P(T^{-2}k^2 a_T^4 l_T) = O_P(T^{-1}k a_T^4) \end{aligned}$$

using $\sum_{i=1}^{\infty} i \|\gamma_{i:k}\| \leq k^2 \|\gamma\|_1 + k \sum_{i=1}^{\infty} i |\gamma_i| = O(k^2)$, so $\|S_{0\varepsilon}^{k\dagger} - \sigma_2^{\dagger}\| = O_{P^{\dagger}}(T^{-1/2} k^{1/2} a_T^2)$ in P -probability. Adding $\|\sigma_2^{\dagger}\| = o_{P^{\dagger}}(a_T)$ completes the proof in the case where π is equal to the identity. \square

A.5 MULTIPLE RESTRICTIONS

Consider the Wald statistic W and its bootstrap counterparts W^* and W_Δ^* defined in Remark 4.2(ix). As in the proof of Theorem 3, and using repeatedly the notation introduced there in what follows, define the r.v.'s

$$\begin{aligned} W^\dagger & : = T\sigma_T^{-2}L_k(S_{00}^{\dagger k})^{-1}S_{0\varepsilon}^{\dagger k}[L_k(S_{00}^{\dagger k})^{-1}L'_k]^{-1}L_k(S_{00}^{\dagger k})^{-1}S_{0\varepsilon}^{\dagger k}, \\ \check{W} & : = T\sigma_T^{-2}L_k(\check{S}_{00}^k)^{-1}\check{S}_{0\varepsilon}^k[L_k(\check{S}_{00}^k)^{-1}L'_k]^{-1}L_k(\check{S}_{00}^k)^{-1}\check{S}_{0\varepsilon}^k, \\ W^{\pi k} & : = T\sigma_T^{-2}L_k(S_{00}^{\pi k})^{-1}S_{0\varepsilon}^{\pi k}[L_k(S_{00}^{\pi k})^{-1}L'_k]^{-1}L_k(S_{00}^{\pi k})^{-1}S_{0\varepsilon}^{\pi k}. \end{aligned}$$

The following sequential distances can then be evaluated in place of those in the proof of Theorem 3.

1. As in step 1 of that proof, it holds that $\rho_L(\mathcal{L}^*(W^*), \mathcal{L}^\dagger(W^*)) = 0$ and $\rho_L(\mathcal{L}^*(W_\Delta^*), \mathcal{L}^\dagger(W_\Delta^*)) = 0$.

2. We argue below that, for the wild bootstrap, $W_\Delta^* = W^\dagger + o_{P^\dagger}(T\tilde{a}_T^2 a_T^{-4})$ in P -probability, so

$$\rho_L(\mathcal{L}^\dagger(a_T^4 \tilde{a}_T^{-2} T^{-1} W_\Delta^*), \mathcal{L}^\dagger(a_T^4 \tilde{a}_T^{-2} T^{-1} W^\dagger)) = o_P(1), \quad (\text{A.1.33})$$

whereas for an r.p. π , $W^* = W^\dagger + o_{P^\dagger}(T\tilde{a}_T^2 a_T^{-4})$ in P -probability, so

$$\rho_L(\mathcal{L}^\dagger(a_T^4 \tilde{a}_T^{-2} T^{-1} W^*), \mathcal{L}^\dagger(a_T^4 \tilde{a}_T^{-2} T^{-1} W^\dagger)) = o_P(1). \quad (\text{A.1.34})$$

3(a). As in step 3 of Theorem 3's proof, under bootstrap schemes \mathbf{w}_R it holds that $\rho_L(\mathcal{L}^\varepsilon(S_{00}^{\dagger k}), \mathcal{L}^{|\varepsilon|}(\check{S}_{00}^k)) = 0$ and $\rho_L(\mathcal{L}^\varepsilon(S_{0\varepsilon}^{\dagger k}), \mathcal{L}^{|\varepsilon|}(\check{S}_{0\varepsilon}^k)) = 0$ for symmetric ε_t 's. As a result, $\rho_L(\mathcal{L}^\dagger(a_T^4 \tilde{a}_T^{-2} T^{-1} W^\dagger), \mathcal{L}^{|\varepsilon|}(a_T^4 \tilde{a}_T^{-2} T^{-1} \check{W})) = 0$.

3(b). Under scheme (π_R, \mathbf{w}_1) , it holds that $W^\dagger = \check{W}$ algebraically.

4(a). Under symmetry of the distribution of ε_t , similarly to step 2,

$$L_k(\check{S}_{00}^k)^{-1}\check{S}_{0\varepsilon}^k = L_k(S_{00}^{\pi k})^{-1}S_{0\varepsilon}^{\pi k} + o_{P^{|\varepsilon|}}(a_T^{-2}\tilde{a}_T + \mathbb{I}_{\pi=r.p.}T^{\varepsilon-1/2}a_T^{-1}k^{1/2}a_k),$$

$$\begin{aligned} [L_k(\check{S}_{00}^k)^{-1}L'_k]^{-1}L_k(\check{S}_{00}^k)^{-1}\check{S}_{0\varepsilon}^k & = [L_k(S_{00}^{\pi k})^{-1}L'_k]^{-1}L_k(S_{00}^{\pi k})^{-1}S_{0\varepsilon}^{\pi k} \\ & \quad + o_{P^{|\varepsilon|}}(\tilde{a}_T + \mathbb{I}_{\pi=r.p.}T^{\varepsilon-1/2}a_T k^{1/2}a_k), \end{aligned}$$

in P -probability, so $\rho_L(\mathcal{L}^{|\varepsilon|}(a_T^4 \tilde{a}_T^{-2} T^{-1} \check{W}), \mathcal{L}^{|\varepsilon|}(a_T^4 \tilde{a}_T^{-2} T^{-1} W^{\pi k})) = o_P(1)$. In the case where π is the identity, using

$$\begin{aligned} \hat{\sigma}_{T_k}^{-2}\sigma_T^2 & = 1 + \hat{\sigma}_{T_k}^{-2}(\|\hat{\varepsilon} - \varepsilon\|^2 + 2\sum \hat{\varepsilon}_t(\varepsilon_t - \hat{\varepsilon}_t)) \\ & \leq 1 + \hat{\sigma}_{T_k}^{-2}(\|\hat{\varepsilon} - \varepsilon\|^2 + 2\hat{\sigma}_{T_k}\|\hat{\varepsilon} - \varepsilon\|) \\ & = 1 + O_P(a_T^{-2}(a_k^2 a_T^\varepsilon + a_k a_T^{1+\varepsilon})) = 1 + O_P(a_k a_T^{\varepsilon-1}) \end{aligned}$$

for $\varepsilon > 0$, we can conclude that $W^{\pi k}$ equals $\hat{\sigma}_{T_k}^{-2}\sigma_T^2 W = W + o_{P^{|\varepsilon|}}(W) = W + o_{P^{|\varepsilon|}}(a_T^{-4}\tilde{a}_T^2 T)$, resulting in

$$\rho_L(\mathcal{L}^{|\varepsilon|}(a_T^4 \tilde{a}_T^{-2} T^{-1} \check{W}), \mathcal{L}^{|\varepsilon|}(a_T^4 \tilde{a}_T^{-2} T^{-1} W)) = o_P(1).$$

In the case of an r.p. π , $\hat{\sigma}_{T_k}^{-2}\sigma_T^2 W$ conditional on $\{|\varepsilon_t|\}_{t=-\infty}^k$ and the order statistics of $\{|\varepsilon_t|\}_{t=k+1}^T$ is distributed like $W^{\pi k}$ conditional on $\{|\varepsilon_i|\}_{i=-\infty}^T$, so

$$\rho_L(\mathcal{L}^{|\varepsilon|}(a_T^4 \tilde{a}_T^{-2} T^{-1} \check{W}), \mathcal{L}^{|\varepsilon|}(a_T^4 \tilde{a}_T^{-2} T^{-1} W)) = o_P(1).$$

As $\hat{\sigma}_{T_k}^{-2}\sigma_T^2 TW = TW + o_{P^{|\varepsilon|}}(W)$, also

$$\rho_L(\mathcal{L}^{|\varepsilon|}(a_T^4 \tilde{a}_T^{-2} T^{-1} \check{W}), \mathcal{L}^{|\varepsilon|}(a_T^4 \tilde{a}_T^{-2} T^{-1} W)) = o_P(1).$$

4(b). Under scheme $(\boldsymbol{\pi}_R, \mathbf{w}_1)$, similarly to step 2,

$$L_k(\check{S}_{00}^k)^{-1}\check{S}_{0\varepsilon}^k = L_k(S_{00}^{\pi k})^{-1}S_{0\varepsilon}^{\pi k} + o_{P^\dagger}(a_T^{-2}\tilde{a}_T + \mathbb{I}_{\pi=r.p.}T^{\varepsilon-1/2}a_T^{-1}k^{1/2}a_k),$$

$$\begin{aligned} [L_k(\check{S}_{00}^k)^{-1}L'_k]^{-1}L_k(\check{S}_{00}^k)^{-1}\check{S}_{0\varepsilon}^k &= [L_k(S_{00}^{\pi k})^{-1}L'_k]^{-1}L_k(S_{00}^{\pi k})^{-1}S_{0\varepsilon}^{\pi k} \\ &\quad + o_{P^\dagger}(\tilde{a}_T + \mathbb{I}_{\pi=r.p.}T^{\varepsilon-1/2}a_Tk^{1/2}a_k) \end{aligned}$$

in P -probability. As $\hat{\sigma}_{T_k}^{-2}\sigma_T^2W$ conditional on $\{\varepsilon_t\}_{t=-\infty}^k$ and the order statistics of $\{\varepsilon_i\}_{i=k+1}^T$ is distributed like $W^{\pi k}$ under P^\dagger , it follows that

$$\rho_L(\mathcal{L}^\dagger(a_T^4\tilde{a}_T^{-2}T^{-1}\check{W}), \mathcal{L}^e(a_T^4\tilde{a}_T^{-2}T^{-1}W)) = o_P(1).$$

Finally, $\hat{\sigma}_{T_k}^{-2}\sigma_T^2W = W + o_{P^e}(W)$, so also

$$\rho_L(\mathcal{L}^\dagger(a_T^4\tilde{a}_T^{-2}T^{-1}\check{W}), \mathcal{L}^e(a_T^4\tilde{a}_T^{-2}T^{-1}W)) = o_P(1).$$

Then we combine the previous distances using the triangle inequality to conclude that

$$\begin{aligned} \text{for } \boldsymbol{\pi}_{id} &: \rho_L(\mathcal{L}^*(a_T^4\tilde{a}_T^{-2}T^{-1}W_\Delta^*), \mathcal{L}^{|\varepsilon|}(a_T^4\tilde{a}_T^{-2}T^{-1}W)) = o_P(1), \\ \text{for } \boldsymbol{\pi}_R, \mathbf{w}_R &: \rho_L(\mathcal{L}^*(a_T^4\tilde{a}_T^{-2}T^{-1}W^*), \mathcal{L}^{|\varepsilon|}(a_T^4\tilde{a}_T^{-2}T^{-1}W)) = o_P(1), \\ \text{for } \boldsymbol{\pi}_R, \mathbf{w}_{id} &: \rho_L(\mathcal{L}^*(a_T^4\tilde{a}_T^{-2}T^{-1}W^*), \mathcal{L}^e(a_T^4\tilde{a}_T^{-2}T^{-1}W)) = o_P(1). \end{aligned}$$

These are equivalent to the convergence asserted in Remark 4.2.(ix).

The argument for Step 2 above can be structured as follows. First, the following refinement of Lemma 3(c) can be proved similarly to that lemma (we skip the details).

LEMMA A.3 *Let $k^4/T + 1/k \rightarrow 0$ and Assumption 1 hold. Then it holds that:*

(a) *For an r.p. π , $\|S_{0\varepsilon}^{k^\dagger}\| = O_{P^\dagger}((k + a_k^{1+\varepsilon})\tilde{a}_T)$ in P probability, for every $\varepsilon > 0$.*

Moreover, as in Lemma 1, let the selection matrix L has δ' -summable rows under linear weighting (i.e. such that $\sum_{j=1}^\infty j|l_{ij}|^{\delta'} < \infty$, $i = 1, \dots, m$) for some $\delta' \in (\delta, \frac{2\alpha}{2+\alpha})$, with δ as defined in Assumption 1. Then:

(b) *For an r.p. π , $\|(L\Sigma^{-1})_k S_{0\varepsilon}^{\dagger k}\| = O_{P^\dagger}(\tilde{a}_T l_T)$ in P probability, where $l_T = 1$ for $\alpha \neq 1$ and l_T is slowly varying for $\alpha = 1$.*

(c) *For π equal to the identity, $\|(L\Sigma^{-1})_k S_{0\varepsilon}^{\dagger k}\| = O_{P^\dagger}(a_T^{1+\varepsilon})$ in P probability, for every $\varepsilon > 0$.*

Next, it can be used to derive the following expansions.

LEMMA A.4 *Under Assumption 1 and the δ' -summability assumption of Lemma 1, it holds in P probability that, for small $\varepsilon > 0$,*

$$L_k(S_{00}^{\dagger k})^{-1}S_{0\varepsilon}^{\dagger k} = \sigma_T^{-2}(L\Sigma^{-1})_k S_{0\varepsilon}^{\dagger k} + o_{P^\dagger}(a_T^{-\varepsilon-1}) = o_{P^\dagger}(a_T^{\varepsilon-1})$$

if π is the identity and $k^4/T + 1/k \rightarrow 0$, whereas

$$L_k(S_{00}^{\dagger k})^{-1}S_{0\varepsilon}^{\dagger k} = \sigma_T^{-2}(L\Sigma^{-1})_k S_{0\varepsilon}^{\dagger k} + o_{P^\dagger}(a_T^{-2}\tilde{a}_T) = o_{P^\dagger}(a_T^{-2}\tilde{a}_T l_T)$$

if π is an r.p., $k^5/T + 1/k \rightarrow 0$ and for $\alpha \leq 1$, also $k^{3+2/\alpha+\zeta}/T \rightarrow 0$ for some $\zeta > 0$.

Finally, (A.1.33) and (A.1.34) can be obtained as follows. Similarly to the argument for Step 2 in the proof of Theorem 3, it can be shown that

$$L_k(\hat{\beta}_k^* - \hat{\beta}_k + \mathbb{I}_{\pi=id}\Delta\hat{\beta}_k^*) = L_k(S_{00}^{*k})^{-1}(S_{0\varepsilon}^{*k} - \sigma_1^{id}) \quad (\text{A.1.35})$$

$$\begin{aligned} &= L_k(S_{00}^{\dagger k})^{-1}S_{0\varepsilon}^{\dagger k} + o_{P^\dagger}(a_T^{-1-\varepsilon} + \mathbb{I}_{\pi=r.p.}T^{\varepsilon-1/2}a_T^{-1}k^{1/2}a_k), \\ & [L_k(S_{00}^{*k})^{-1}L'_k]^{-1}L_k(\hat{\beta}_k^* - \hat{\beta}_k + \mathbb{I}_{\pi=id}\Delta\hat{\beta}_k^*) \quad (\text{A.1.36}) \\ &= [L_k(S_{00}^{\dagger k})^{-1}L'_k]^{-1}L_k(S_{00}^{\dagger k})^{-1}S_{0\varepsilon}^{\dagger k} + o_{P^\dagger}(a_T^{1-\varepsilon} + \mathbb{I}_{\pi=r.p.}T^{\varepsilon-1/2}a_Tk^{1/2}a_k), \end{aligned}$$

It also holds that

$$\begin{aligned} |\sigma_{T_k}^{*2} - \hat{\sigma}_{T_k}^2| &\leq (\hat{\beta}_k^* - \hat{\beta}_k)' S_{00}^{*k} (\hat{\beta}_k^* - \hat{\beta}_k) + 2\hat{\sigma}_{T_k} [(\hat{\beta}_k^* - \hat{\beta}_k)' S_{00}^{*k} (\hat{\beta}_k^* - \hat{\beta}_k)]^{1/2} \\ &= S_{\varepsilon 0}^{*k} (S_{00}^{*k})^{-1} S_{0\varepsilon}^{*k} + 2\hat{\sigma}_{T_k} [S_{\varepsilon 0}^{*k} (S_{00}^{*k})^{-1} S_{0\varepsilon}^{*k}]^{1/2} \end{aligned}$$

so $|\sigma_{T_k}^{*2} - \hat{\sigma}_{T_k}^2| = o_{P^\dagger}(a_k^{1+\varepsilon}\tilde{a}_T)$ for $\pi = id$ and $|\sigma_k^{*2} - \hat{\sigma}_k^2| = O_{P^\dagger}((k + a_k)\tilde{a}_T)$ for an r.p. π , in P -probability, for all $\varepsilon > 0$. As $|\hat{\sigma}_{T_k}^2 - \sigma_{T_k}^2| = o_P(a_k a_T^{1+\varepsilon})$, all $\varepsilon > 0$ (see equation (10) and (A.1.16)), it follows that

$$\sigma_k^{*2} = \sigma_T^2 + o_{P^\dagger}(a_k a_T^{1+\varepsilon} + \mathbb{I}_{\pi=r.p.}k a_T^{1+\varepsilon}). \quad (\text{A.1.37})$$

From (A.1.35) and (A.1.36), using that the eigenvalues of $S_{00}^{\dagger k}$ have exact magnitude order a_T^2 in P^\dagger, P probability, and $L_k(S_{00}^{\dagger k})^{-1}S_{0\varepsilon}^{\dagger k} = O_{P^\dagger}(a_T^{\varepsilon-1})$ for $\pi = id$ and $\varepsilon > 0$ (by Lemma A.4), it follows that for small $\varepsilon > 0$,

$$T^{-1}\sigma_{T_k}^{*2}W_\Delta^* = L_k(S_{00}^{\dagger k})^{-1}S_{0\varepsilon}^{\dagger k}[L_k(S_{00}^{\dagger k})^{-1}L'_k]^{-1}L_k(S_{00}^{\dagger k})^{-1}S_{0\varepsilon}^{\dagger k} + o_{P^\dagger}(a_T^{-\varepsilon}) = o_{P^\dagger}(a_T^\varepsilon)$$

for the wild bootstrap, if $k^4/T \rightarrow 0$. Upon division by σ_k^{*2} and its approximation by σ_T^2 according to (A.1.37), it is obtained that $W_\Delta^* = W^\dagger + o_{P^\dagger}(T\tilde{a}_T^2 a_T^{-4})$ and, as a consequence, equation (A.1.33) holds.

If π is an r.p., independently of the specification of $\{w_t\}_{t=k+1}^T$, equations (A.1.35) and (A.1.36) specialize to

$$L_k(\hat{\beta}_k^* - \hat{\beta}_k) = L_k(S_{00}^{\dagger k})^{-1}S_{0\varepsilon}^{\dagger k} + o_{P^\dagger}(a_T^{-1-\varepsilon} + T^{\varepsilon-1/2}a_T^{-1}k^{1/2}a_k),$$

$$\begin{aligned} [L_k(S_{00}^{*k})^{-1}L'_k]^{-1}L_k(\hat{\beta}_k^* - \hat{\beta}_k) &= [L_k(S_{00}^{\dagger k})^{-1}L'_k]^{-1}L_k(S_{00}^{\dagger k})^{-1}S_{0\varepsilon}^{\dagger k} \\ &+ o_{P^\dagger}(a_T^{1-\varepsilon} + T^{\varepsilon-1/2}k^{1/2}a_k a_T). \end{aligned}$$

As now $L_k(S_{00}^{\dagger k})^{-1}S_{0\varepsilon}^{\dagger k} = O_{P^\dagger}(a_T^{-2}\tilde{a}_T l_T)$ under the hypotheses of Lemma A.4, it follows that, if $k^5/T \rightarrow 0$ (and for $\alpha \leq 1$, also $k^{3+2/\alpha+\zeta}/T \rightarrow 0$ for some $\zeta > 0$), then for sufficiently small $\varepsilon > 0$,

$$T^{-1}\sigma_{T_k}^{*2}W^* = L_k(S_{00}^{\dagger k})^{-1}S_{0\varepsilon}^{\dagger k}[L_k(S_{00}^{\dagger k})^{-1}L'_k]^{-1}L_k(S_{00}^{\dagger k})^{-1}S_{0\varepsilon}^{\dagger k} + o_{P^\dagger}(a_T^{-\varepsilon})$$

is $o_{P^\dagger}(a_T^\varepsilon)$ in P probability. As previously, jointly with (A.1.37) this leads to $W^* = W^\dagger + o_{P^\dagger}(T\tilde{a}_T^2 a_T^{-4})$ and, hence, (A.1.34) follows.
