# Due Diligence and Investee Performance

## Abstract

Our study provides new evidence on due diligence (DD) and its impact on investee performance. We estimate the economic value of due diligence (DD) in the context of private equity (PE) by investigating the relationship between DD and investee performance, while controlling for endogeneity. With the adoption of a novel and unique dataset, we find evidence highly consistent with the view that a thorough DD is associated with improved future investee performance. We also distinguish the role of different types of DD and show that the DD carried out internally by fund managers has a more pronounced impact on performance. Instead, the DD mainly performed by external agents, such as consultants, lawyers and accountants, gives rise to puzzling results and imperfect matching, highlighting the existence of apparent agency problems.

*JEL Classification:* G23, G24, G28

*Keywords:* Due Diligence, Governance, Performance, Private Equity

“What we hope ever to do with ease, we must learn first to do with diligence.”

## **1. Introduction**

This study aims at empirically investigating the determinants and economic value of due diligence (DD) in the context of private equity (PE) financing, as well as the impact of different types of DD (e.g., internal vs. external) on firm performance. Despite the emphasis placed on the importance of DD by various industry guides and venture capital associations (e.g., the European Venture Capital Association, the National Venture Capital Association, and the Canadian Venture Capital Association), very few academic studies have investigated its efficacy and economic value. For the purpose of this paper, we adopt the term “private equity” to refer to the later stage financing of existing firms, in line with the definition provided by the Italian Venture Capital Association (AIFI), Capizzi (2004), and Heed (2010), among others. This definition, which differs from the one typically adopted in USA (see, e.g., Korteweg and Sorensen, 2014), excludes the funding of start-up and early stage firms (venture capital investments) and includes: a) development or expansion financing b) leveraged buyout (LBO) deals, and c) replacement and turnaround financing (see, e.g., Zambelli, 2010; 2014). Historically, the PE sector has dominated the Italian alternative financing industry, while early stage investments have always represented a minority (see AIFI Statistics Reports from 1999 onwards, Caselli *et al.*, 2013).

Research in entrepreneurial finance has stressed the importance of due diligence, but primarily from a theoretical perspective (Yung, 2009). While empirical studies to date have emphasized the importance of investor characteristics, reputation, and cultural differences among venture capital (VC) and private equity (PE) intermediaries (Casamatta and Haritchabalet, 2007; Caselli *et al.*, 2013; Das *et al.*, 2010; Masulis and Nahata, 2009, Nahata, 2008; Nahata *et al.*,

2013; Sevilir, 2010), no empirical studies have formally examined the economic value and impact of DD. Related research in corporate finance (Li and Prabhala, 2006) and entrepreneurial finance (Sorensen, 2007; Yung, 2009; Bengtsson and Hsu, 2012) has focused on selection models. However, there have been no empirical studies examining the financial importance of selection and matching investors and investees in a PE setting. Also, little evidence exists on how such screening takes place and who exactly carries out due diligence. In this paper, we provide some of the first evidence on screening by empirically investigating the determinants and the economic value of the due diligence in the context of private equity (PE) financing. Moreover, we provide a novel look at the impact of different types of due diligence (e.g., internal vs. external) on firm performance. We compare the role of lawyers, accountants, and consultants carrying out due diligence to assess whether there are agency costs associated with delegating due diligence.

As highlighted by Brown *et al.* (2008, 2009, 2012), due diligence is crucial for hedge fund and other types of alternative investments, including but not limited to PE financing. Likewise, we would expect that due diligence is particularly important in PE financing where value-added fund managers are actively involved in the governance and management of their portfolio companies (Gorman and Sahlman, 1989; Gompers and Lerner, 1999; Casamatta, 2003; Inderst and Muller, 2004; Yung, 2009; Ivanov and Xie, 2010). Also, private equity funds are generally not well diversified and, as such, fund managers take extra care to mitigate idiosyncratic risks (Kannianen and Keuschnigg, 2003, 2004; Nahata, 2008; Nielsen, 2008; Knill, 2009; Wang and Wang, 2011, 2012; Altintig *et al.*, 2013; Nahata *et al.*, 2013).

In the context of our analysis, due diligence refers to the investigation process of a prospective investment in a particular target firm by PE investors (hereafter venture capitalists, or VCs). Due diligence involves a thorough assessment of a number of factors, e.g., management skills, target industry and competitors, project opportunity, financial forecasts, and strategic fit

with the fund portfolio companies (Camp, 2002), as well as operational and financial risk (Brown *et al.* 2008). This evaluation process may be performed mainly internally by PE fund managers themselves (“internal DD”) or mainly externally by strategic and financial consultants, or law and accountancy firms (“external DD”). For the purpose of this study, when we use the terms “internal” or “external” due diligence we refer to the agents (internal or external) who performed the *majority* of the due diligence process (not the entire process). These activities are not mutually exclusive and may act as complements. For example, an “internal” DD refers to a situation in which the *majority* of the DD is performed by the PE investor internally and it is possible that a small part of this activity (e.g., the legal DD) is delegated externally (see Table 1 for more details on the definitions of the different types of DD adopted in our study).

A rigorous due diligence is costly and takes time. Expenses for due diligence include direct costs of paying for information pertaining to the investee, legal costs for background checks, and the value of time spent on the due diligence. Indirect costs of due diligence include the potential lost opportunity in terms of the investee walking away from the deal or getting financing elsewhere. Indirect costs likewise include opportunity costs on time not spent considering other potential projects, or time not spent on adding value to other firms in a fund’s portfolio. Considering the costs, time and effort involved, important research questions are: a) How worth is the time spent on implementing it?; b) Would it be better to save time and delegate this investigation process to external agents (e.g., strategic consultants, law firms, or accountants)? As highlighted by Camp (2002), the main reason underlying such deep investigation of prospective investments in target companies is that, by doing so, VCs hope to make better investment decisions, and thereby enhance the returns on their overall portfolios. However, considering the direct and indirect costs involved, PE investors may be tempted to rush

the DD process or to delegate it to external agents and it is not exactly clear as to whether or not additional due diligence is worth it in terms of performance payoffs.

Despite the existence of a vast literature on selection criteria (for a recent review see, e.g., Alemany and Villanueva, 2014), no prior study has empirically investigated the economic value of DD and its efficacy with reference to how much the investment in due diligence pays in terms of obtaining better future performance from the investee. The importance and the costs of due diligence for PE funds have been examined solely from a theoretical perspective by Yung (2009), who argues that due diligence facilitates matching and mitigates adverse selection problems. To the best of our knowledge no prior study has empirically examined the relationship between PE due diligence and investment performance. Partial exceptions are Wangerin (2015), who analyzes the DD in the context of M&A transactions, Brown *et al.* (2008), who investigated the role of due diligence solely for hedge funds, Sorensen (2007), who estimates the impact of sorting and matching in the context of investments made in early stage and startup companies, and Baum and Silverman (2004), who examined the screening role of VC funds by focusing only on the biotechnology industry and start-up firms. These studies highlight the need for further and broader research on the selection process in PE settings.

In this paper, we contribute to filling this gap by empirically assessing the efficacy and time-value of DD through the adoption of a novel and unique hand-collected dataset, which covers the majority of the funds actively involved in the Italian PE market, whose transactions experienced relevant legal changes that affected their frequency and the allocation of attention of PE funds.<sup>1</sup> More specifically, we investigate the economic value of an additional week of DD, and account for the role played by the particular agent performing such DD (i.e., PE fund

---

<sup>1</sup> See Heed (2010) and Nahata *et al.* (2013) for related studies investigating the impact of the legal environment in PE finance; see Zambelli (2010) for details regarding the changes experienced by the PE legal setting in Italy.

managers, external legal advisors, chartered accountants, or other external consultants). Sorensen (2007) provides a matching model without any empirical analysis of factors pertinent to internal versus external due diligence or the extent of internal versus external due diligence. Our study is the first to empirically evaluate this aspect.

In terms of outcomes, the key performance measures underlying our study are related to investee firms. In line with Richard *et al.* (2009) and Kabir and Roosenboom (2003), for each investee firm we track two operating performance indicators over the first three years from the investment date: the Return on Assets (ROA) and the operating profit margin (EBITDA to Sales ratio, hereafter EBITDA/Sales), as measures of operating profitability. These performance measures on a firm level are also consistent with Caselli *et al.* (2013), and Cao (2013).<sup>2</sup> The key independent variable underlying our study is represented by the time spent on due diligence, considered as a proxy of the importance and effort given by the investor to that particular activity, in line with a recent tendency in the entrepreneurial field (e.g., Wangerin 2015; Achleitner *et al.*, 2014).<sup>3</sup>

---

<sup>2</sup> It is worth noting that other performance measures on a fund level could be considered (IRR and IPO exit). However, we decided to focus on ROA and EBITDA/SALES because we want to measure 3-year performance from date of investment to have a uniform measure of performance that can be reasonably connected to due diligence. IRRs are difficult to use, as many firms will not have had an exit within 3 years, and hence IRRs are based on imprecise valuations which are often wrong (Cumming and Walz, 2010). And because we look at a 3 years horizon where many firms do not yet have an exit, we cannot examine IPOs. Moreover, as highlighted in Caselli *et al.* (2013), ROA and EBITDA/SALES do not heavily depend on market conditions as IRR does (which is influenced by the entry and exit prices paid by the PE fund). The IPO exit is also a coarse measure of an investment outcome (i.e., ROA and EBIT/Sales can vary widely across different IPOs), despite his wide usage, as highlighted by Sorensen (2007). Nevertheless, for robustness purposes in Section 6.4. we do show results on the impact of DD on IPOs, and the findings are consistent.

<sup>3</sup> We decided to use the time spent on DD as a proxy of the importance given by investors to the DD activity and their effort in implementing such activity. The intuition behind this decision is that the time dedicated to a certain activity can capture the role and importance that this activity plays for a particular agent. This is especially true for the PE industry where the opportunity cost of time is enormous and PE investors may be tempted to rush the due diligence activity of perspective investments in order to allocate more attention to managing and adding value to existing portfolio firms. By looking at the high variability in the time spent on DD among different PE investors and within the same PE fund, we imply that such difference can effectively capture a different level of effort, which differs on a case-by-case basis. The more time and attention a fund manager allocates to the due diligence of a certain firm, more resources the fund is allocating to that firm, and this captures the underlying importance given by such investor to the activity of due diligence. This is also in line with a recent evidence in the entrepreneurial finance field

Our empirical analyses consistently highlight the efficacy and importance of due diligence in improving firm performance (especially if the due diligence activity is carried out by internal fund managers). Our results are highly consistent with the view that the time spent on due diligence has substantial economic value, and reinforces the implications underlying the theoretical model of Yung (2009), and the evidence provided by Brown *et al.* (2008; 2012). Overall, an extra week of due diligence is statistically associated with higher levels of ROA and EBITDA/Sales over a three-year period after the investment date, even after controlling for endogeneity and other things being equal. PE funds on average carry out seven weeks of due diligence, and our estimates suggest that the effect of an extra four weeks of due diligence is on average associated with a doubling of three-year ROA performance.

Our data also allow us to distinguish the role played by different agents implementing the majority of due diligence. Our findings show that, when the majority of the due diligence is performed internally by PE investment managers, a more pronounced role on firm performance emerges. Surprisingly, when the majority of the due diligence is carried out externally by law firms, accounting firms, and external strategic management consultants there is no significant impact on target firm performance. This result suggests the existence of apparent agency costs associated with external due diligence and emphasizes the need for more theoretical and empirical research in this field. Our study contributes to the literature in several ways. First, it helps advance the knowledge on the role and importance of due diligence. Second, it sheds some light on the economic value of the time spent on due diligence, in terms of future performance of investee firms. Third, it shows a greater efficacy of the due diligence implemented by PE fund manager, highlighting the existence of agency costs associated to the delegation of such activity

---

(see, e.g., Wangerin 2015, Achleitner *et al.*, 2014) where the time spent in implementing or discussing a certain activity is considered a proxy of the importance of such activity.

This paper is organized as follows. Section 2 reviews the literature and develops testable hypotheses. Section 3 discusses the institutional setting. Section 4 describes the employed research methodology and the dataset, as well as provides representative tests and summary statistics. Sections 5 and 6 present the univariate and multivariate tests, respectively. The last section provides concluding remarks and suggestions for future research.

## **2. Related Literature and Testable Hypotheses**

Our paper is related to three main streams of literature. The first stream pertains to the literature directly related to due diligence in terms of the value of screening. The second stream pertains to matching models. The third pertains to the private equity literature in terms of the drivers of performance. In this section we briefly discuss each in turn.

Our paper is most closely related to Yung's (2009) theoretical model of the tradeoffs associated with undertaking costly due diligence. One of the main reasons underlying the existence of private equity funds is that banks and other financial intermediaries offering more traditional sources of capital are unable to perform, in a cost effective manner, the screening required to undertake due diligence and monitor an investee that exhibits significant adverse selection costs (Yung, 2009). Adverse selection costs of attracting excessively risky companies are particularly pronounced for banks and other loan sources of capital (Stiglitz and Weiss, 1981). As a result, private equity funds that are able to mitigate adverse selection by undertaking costly due diligence are in a better position to finance such investee companies. Moreover, the investee companies that are able to incur costly signals of quality are more likely to obtain funding. Costly due diligence is typically more effective than costly signals of quality incurred by target companies because the latter are cash constrained while investors are in a better position to incur costs of due diligence (Yung, 2009).

How entrepreneurial firms and private equity funds form matches has been the subject of recent scholarly research (Bengtsson and Hsu, 2012). Matching models more generally are useful in this regard because they enable evaluation of selection effects distinguished from other effects such as value-added. Sorenson (2007) uses general matching models to empirically study the importance of matching and finds that matching is roughly twice as important as private equity experience, in terms of explaining IPO exit outcomes (see Li *et al.*, 2006 for a survey of these models). Empirical studies in venture capital and private equity have examined both screening and the drivers of returns. Kaplan and Stromberg (2004) study screening in terms of factors considered in due diligence and provide examples of what led an investor to invest in the context of venture capital deals. Drivers of returns are studied in numerous papers, such as Nahata (2008), Cao and Lerner (2009), and Chaplinsky and Haushalter (2010).

Our context is quite different, since we study private equity deals and measure the extent of due diligence and who exactly carried out the due diligence (internally, or externally by an accounting firm, law firm, or consulting firm). Prior work has not studied the link between the duration of due diligence effort and PE investee performance. Prior work in the context hedge funds shows that due diligence is a source of alpha (Brown *et al.*, 2008; 2009; 2012). Brown *et al.*, however, do not consider the extent of due diligence effort in terms of the time, but rather examine materials related to registration statements. Our paper is different insofar as we measure screening by the extent of due diligence, and relate this due diligence to performance measures pertinent to the entrepreneurial firm, including ROA and EBITDA/Sales. Guided from the results of Brown *et al.* (2008; 2012), we expect a positive relation between firm performance and due diligence due to the improved decision making over whether to invest, and a better matching between investor and entrepreneur.

**H1:** *There is a positive but diminishing relation between weeks spent on due diligence and investee performance due to improved screening and matching.*

Also, we consider differences in this relationship for different parties that carry out due diligence. Guided from the implications underlying Yung's (2009) theoretical model, we expect that internal due diligence is more effective than external due diligence for the purpose of the matching function between entrepreneurs and their investors. The intuition is that external due diligence service providers such as accounting firms, law firms and consulting firms face information asymmetries associated with the skills of the private equity fund and its fund managers, thereby leading to imperfect knowledge in matching with entrepreneurial teams. By contrast, private equity fund managers face no information asymmetries about themselves, and only face the same information asymmetries that external service providers face vis-à-vis the entrepreneurial team. If the ability of the internal management team is the same as the ability of the external consultants in mitigating the information asymmetries with the entrepreneurial team, then the private equity fund managers will be more effective at finding a more suitable match than the external consultants.

**H2.** *When due diligence is primarily done internally (as opposed to primarily done externally by a law firm, accounting firm, or consulting firm), there is a stronger link between due diligence and performance due to the improved matching of the investor and the entrepreneur.*

In respect of H2, we note that different external service providers (accounting firms, law firms, and consulting firms) may have different abilities in terms of mitigating information asymmetries vis-à-vis the entrepreneurial firms. If so, we would expect different results depending on who carries out the due diligence. We do not conjecture who is most effective in advance of presenting the data, but we do carry out such tests in the analysis of the data.

These above hypotheses are tested for the first time in the subsequent sections. Our tests are based on unique and detailed data that are described below in section 4. The data are based on the Italian private equity industry, and as such in section 3 we first describe the institutional context from which the data are derived.

### **3. Institutional Context Affecting the Italian PE Industry**

Buyout transactions in Italy experienced a period of uncertain legitimacy and illegality and only recently did they become outright legal (with the issuance of the new corporate governance law, Legislative Decree 6/2003, applicable as of January 1, 2004; for details see Zambelli, 2010).

Over the '90s, the legitimacy of leveraged buyouts were severely criticized and highly debated, because LBOs were accused of involving a lack of full disclosure and contributing to the weakening of the target firms. Leveraged buyout transactions even received an illegality declaration by the Italian Supreme Court which prohibited these types of transactions reinforcing the decisions of illegality made by various lower courts in prior years (see the Supreme Court Decision 5503/2000). In October 2001, the Italian Parliament issued a new Bill of Law (Law 366/2001) announcing its intention of reconsidering the buyout legal framework and create a safer harbor for such types of transactions (Article 7d). This Bill of Law 366/2001 was not immediately applicable in Italy as it was solely an enabling act with which the Government received the power of legalizing leveraged buyouts under specific guidelines. Even though this Bill of Law provided investors with some hope for a more favorable LBO legal harbor, there was no certainty regarding dates and outcomes of the new buyout reform. Moreover, in 2002, a new criminal law reform (Legislative Decree 61/2002) became effective introducing new prosecutions applicable to LBOs in the case of bankruptcy of the target firms. In January 1, 2004, a new law

came into force and leveraged buyouts were legalized under a set of conditions, especially with reference to disclosure (see the article 2501 bis, of the Legislative Decree 6/2003, applicable as of January 1, 2004). Contrary to what occurred in previous years, the new LBO reform reversed the burden of proof: LBOs are now considered legal until proven otherwise (see Zambelli, 2010 for more details). For the investment period spanning 1999–2006, it is possible to identify three different sub-periods, associated with a number of changes in legal settings experienced by the Italian PE industry. As shown in Cumming and Zambelli (2010), these legal changes significantly affected the frequency and the governance structure of PE transactions in Italy and, as such, it is plausible to expect that they may also affect the DD time and the type of DD performed by PE funds.

In order to account for these legal changes we have created three different dummy variables that are metaphorically labeled: “Dark period”, “Hope period”, and “Sun period” (as in Cumming and Zambelli 2010, 2013). In our data, the “Dark period” identifies the period of illegality and represents the time span from January 1999 to September 2001 over which the legitimacy of leveraged buyouts was highly disputed and LBOs were deemed illegal by the Italian Supreme Court (for a detailed discussion on the reasons and case law underlying the illegality of LBOs in Italy, see Zambelli, 2010). The subsequent period, characterized by Parliament’s announcement of rendering LBOs legal, is instead labeled the “Hope period”, and it covers the October 2001–December 2003 time horizon. The period subsequent to January 2004 (and ending July 2006 in our data) identifies the time horizon over which LBOs became legal. This particular period is labeled the “Sun period” (or period of legality) and represents the period over which the legitimacy of LBO was ultimately clarified.

The different institutional settings provide useful instruments for our empirical analyses below. We expect a weaker DD over the Dark period, since PE funds in that period are aimed at

minimizing the risk of a legal dispute with the target firm that could end up with an illegality declaration. The threat of a legal dispute at that time may distort the investors' incentives to implement a thorough DD. Over the dark period, PE investors have obvious legal incentives to not invest in hostile targets (as shown in Cumming and Zambelli 2010). Cumming and Zambelli (2010) show the perils of a restrictive regulation. They show how the periods of illegality and uncertain legality in Italy have increased the incentives for PE investors to implement a distorted due diligence of target firms, because PE investors seem to be more motivated to screen firms according to the level of agreeableness with their target management and minority shareholders in the hopes of reducing the risk of a subsequent legal dispute that could turn into an illegality declaration of the entire acquisition process.

#### **4. Data**

One of the major problems faced by scholars in PE financing is the lack of detailed public data. Typically, PE organizations and their investee companies are privately held and are not required to disclose detailed information on their investments, capital structure, governance, and performance. The most commonly used public database on PE financing is Thomson Financial Venture Economics, which is not helpful for our research purpose because it includes solely standard and basic information on PE deals around the world, e.g., target firms, lead investors, syndicated investors, invested and divested amounts, financing rounds, number of investors involved, equity stake, investment location. Moreover, for countries outside the U.S. and Canada, Thomson Financial Venture Economics only includes a small fraction of the PE deals carried out in each year. With reference to the Italian PE market, a few industry datasets exist: a) the AIFI Statistics Report, which disclose aggregate information of the private equity and venture capital activity in Italy; b) the Venture Capital Monitor (VEM), which reports start-up deals; and c) the

Private Equity Monitor (PEM), which reports generic data on the private equity deals. Both VEM and PEM datasets are collected by the Italian Venture Capital Association in association with the Università Cattaneo di Castellanza. The above industry datasets include generic information on the deals carried out in Italy and do not report information on deal structure, due diligence, and investee performance. In the absence of high quality publicly available information on due diligence and investment outcomes, we hand-collected a unique proprietary dataset gathered from a number of primary and secondary sources.

Our primary source of information is represented by a three-stage survey of PE investments carried out in Italy over the 1999-2006 time horizon and related divestments realized from January 2000 to December 2012. For each survey, we followed the methodology discussed in Cumming and Zambelli (2010, 2013). Our secondary sources of information are represented by various publicly available data on Italian PE deals (e.g., PEM database), performance of private firms (e.g., AIDA), market characteristics, fund websites, and economic press release, employed to integrate, cross-check and validate the information collected through the survey instrument (see the Appendix for detailed information on the secondary sources employed).

The data underlying this paper provide unique and new information on due diligence and investee performance, among other things, that were specifically collected for the purpose of this study and not available for use in earlier studies, as described herein. The entire data collection procedure, the survey design and the associated response rates are summarized in Figure 1, and described in greater detail in the Appendix.

[include Figure 1]

In the Appendix we also provide detailed information pertaining to the representativeness of our ultimate dataset by thoroughly discussing different comparison tests. In particular, to evaluate the representativeness of our ultimate sample, we compared our dataset with both AIFI

Statistics Reports and the Private Equity Monitor (PEM<sup>®</sup>) database which includes generic information on PE deals realized in Italy. We performed a number of comparison tests between our sample and the PEM dataset (or AIFI database) with reference to various investee and investment characteristics, such as: area and industry distribution of the target firms, yearly distribution of PE investments, as well as exit distribution of the divestments occurred within the 2000-2012 period. Apart from a few exceptions, we did not find significant differences between our sample and the AIFI and PEM databases (for more details on the representativeness tests, see the Appendix, Table A.1, Panels B–G). The three-stage survey implementation and its validation took considerable time and effort but it ultimately allowed us to create a unique dataset containing detailed information on PE investment cycle, security design, deal structure, and investment outcomes.

Our ultimate dataset covers approximately 85% of the buyout investors operating in Italy over the 1999-2006 investment period (see the Appendix, Panel A), and comprises in depth information on the divestments carried out by PE funds over the 2000-2012 time horizon. Our dataset includes 178 investee firms acquired by 27 PE organizations over the period from 1999 to 2006 (second quarter). Among these 178 PE investments, 150 have been divested within the period from January 2000 and December 2012 (for details on the yearly exit distribution over the 2000-2012 divestment period, see the Appendix, Table 1, Panel E).

In terms of types of exits employed by PE investors, our data show that the most commonly used divestment route is represented by the trade sale (51%), followed by the secondary sale (27%), IPO (9%), and buyback by the entrepreneur or founder (4%). This evidence is consistent with Caselli *et al.* (2013). Our sample also includes a portion of write-offs (10%), mostly associated with the exits that occurred after the global financial crisis (post August 2007 – 2009 period). In terms of type of transactions, our database includes 116 (65%) leveraged

buyouts and 62 (35%) expansion and replacement financing.<sup>4</sup> With reference to investor characteristics, our dataset includes the following types of PE funds: 4 (15%) are Italian bank-subsidaries, 12 (44%) are Italian independent closed-end funds, 3 (11%) are international bank subsidiaries, and the remaining 8 PE firms (30%) are international independent limited partners.

In Table 1 we describe the dependent and explanatory variables included in our dataset and provide related summary statistics. The main dependent variables are represented by firm performance indicators (in terms of Return on Assets - ROA - and EBITDA to Sales ratio, as defined and motivated in Footnote 2), which are measured in terms of percentage difference over the first three years from the investment date. For example, the variable “Return on Assets three-year difference” represents the percentage difference between the ROA achieved by the target firm after three years (ROA 3) from the entrance of the PE investor (investment date) and the ROA at the investment date (ROA 0). Similarly, the variable “Return on Assets two-year Difference” represents the percentage difference between the ROA achieved by the firm after two years (ROA 2) from the investment date and the ROA at the time of the investment (ROA 0).

Table 1 provides statistics on due diligence efforts (measured in terms of time spent in implementing the due diligence) and type of due diligence (primarily internal or external). PE fund managers on average spend 7 weeks on due diligence prior to making a first investment in a portfolio firm. Forty-seven percent of the PE funds in the sample perform the vast majority of the due diligence internally. Sixty-six percent also employ consultants, 68% use lawyers, and 11% use accountants in their due diligence efforts.<sup>5</sup>

---

<sup>4</sup> Our database does not allow to distinguish repeated investments in the same firms. However, as highlighted by Caselli *et al.* (2013), the standard investment strategy generally adopted in Italy by PE investors is “*one firm – one investment*”, which implies that PE funds do not frequently employ stage financing.

<sup>5</sup> It is worth noting that these percentages are not mutually exclusive. For example, a PE fund performing the majority of DD internally can still delegate some part of DD to external specialized agents. In case of delegation, the PE fund can employ different agents (e.g., specialized consultants and/or lawyers and/or accountants).

Table 1 also shows a wide set of other control variables aimed at capturing the impact of: market conditions (i.e., market returns); investment characteristics (e.g., investment values, which represents the transaction value and is used as a proxy for the investment size, and number of syndicated investors for each financing rounds); characteristics of the target firms (i.e. location and industry market to book values; and fund characteristics (i.e., fund-age and number of funds managed by the PE organization before investing in the investee, considered as proxies for fund manager experience; portfolio size, and fund-independency). Table 1 also includes variables that capture the different legal settings during the 1999-2006 investment period in Italy, as explained above in section 3.

[Insert Table 1 About Here]

## 5. Univariate Tests

Table 2 reports comparison of means and medians for our main performance measures described in Table 1 (ROA differences, EBITDA/Sales differences). These performance measures are reported in association with different due diligence time length (i.e., above or below 10 weeks<sup>6</sup>) and different types of due diligence (prevalent internal or external DD; consultants' DD; legal DD; accountants' DD). The comparison of means and median tests are reported for the entire sample (178 transactions).

As reported in Table 2 (Panel A), the target firms for which PE investors spent more time on due diligence (i.e., employing more than 10 weeks) show better performance, consistent with our first hypothesis (H1), even though the differences are significant only in terms of three-year ROA and EBITDA/Sales (the difference in the three-year ROA is significant at the 10% level for both the mean and the median; the difference in the tree-year EBITDA/Sales is significant at the 1% level only for median). Similarly, PE transactions for which PE funds implemented the

---

<sup>6</sup> We also considered different cut-off periods (e.g., the median) and results did not materially change.

majority of due diligence (Panel B) show better firm performance in terms of three-year differences (e.g., the difference in the three-year ROA is significant at the 5% level for the median, and the three-year EBIDTDA/Sale difference is significant at the 1% level for median and 10% level for mean), consistent with our second hypothesis (H2). Panels C–E focus on the performance associated with external due diligence: consultants’ due diligence (Panel C), legal due diligence (Panel D), and accountants’ due diligence (Panel E). The transactions for which the due diligence was delegated to consultancy firms (consultants’ due diligence) or legal firms (legal due diligence), do not show significant differences in terms of performance. It is instead puzzling to notice worse performance associated with the due diligence delegated to chartered accountants (accountants’ due diligence). Only the three-year EBITDA/Sales ratios show a statistically significant difference at the 5% level (in terms of mean).

In Panels F-G of Table 2 we report the comparison tests of means and medians of the time spent on due diligence over the Dark period compared with the due diligence effort over the Hope and Sun periods. As expected, the Dark period is characterized by a weaker due diligence compared with the time spent on due diligence over the Hope and Sun periods and these differences are statistically significant in terms of mean and median. As explained in Section 3, over the Dark period the higher transaction risk regarding the possibility of entering into a legal dispute with the investee may distort the due diligence process by pushing PE investors to focus more on selecting non-hostile targets.

[Insert Table 2 About Here]

## **6. Multivariate Tests**

In this section we present a number of multivariate tests for the impact of due diligence on investment performance. We proceed in three steps. First, we present evidence on the

determinants of weeks of due diligence in subsection 6.1. Second, we present evidence of the impact of due diligence on ROA and EBITDA/Sales in subsection 6.2. Third, we present evidence from subsets of the data based on who carries out due diligence in subsection 6.3. Fourth, in subsection 6.4, we present and discuss the results of a number of additional regression specifications in order to evaluate and confirm the robustness of our main findings.

### *6.1. The Determinants of Due Diligence*

Because the impact of due diligence on investment performance may be affected by endogeneity, we first examine why due diligence is more intensive for some investments but not others. In Table 3 we present correlation statistics across select variables in the data to examine whether or not there are variables that are correlated with due diligence, but unrelated with ROA and EBITDA/Sales. The data highlight the importance of three such variables: the Dark period dummy variable, preplanned IPOs, and the number of funds managed by the PE firm at the time of investment. These findings are in line with intuition, since in the Dark period PE investors focused their attention primarily towards finding non-hostile target firms (Cumming and Zambelli, 2010). Likewise, we expect that preplanned IPOs would impact the intensity of due diligence since an investor would want to more intensively examine a target firm that is supposed to hopefully undergo the scrutiny of a securities regulatory commission in an IPO (Megginson and Weiss, 1991; Levis, 2011; Cumming and Johan, 2013).

Finally, in line with Nahata (2008) and Yung (2009), more experienced investors are naturally more likely to be more diligent in their due diligence. More experienced investors also certify the quality of the entrepreneurial firm upon exit, which can give rise to improvement in performance upon sale of the company (Nahata, 2008). However, our performance measures are not recorded at the time of sale of the company but instead within the 1-3 year period after the

initial investment (for ROA and EBITDA/Sales). More experience could lead to greater value added in the 1-3 year time period; however, such investor value added is more likely to be directed at long term performance to maximize the value of the investee firm at the time of its sale, and not at any point in the interim period (the only reason to maximize value in the interim period prior to exit would be to report inflated investment values to institutional investors, which is something that more experienced investors would not do; see Cumming and Johan, 2013). In short, there is no reason to expect that more experience will affect performance in this 1-3 year time horizon other than through the channel of better and more due diligence. Therefore, since there is no reason to necessarily expect a direct correlation between these three instruments and our performance measures, and given these variables are not significantly correlated with our performance measures, we identify them as candidate instruments for our subsequent analyses of the relationship between due diligence and investee performance. Of course, instrumental variable methods allow consistent estimation when the explanatory variables are correlated with the error terms of a regression relationship, but the error term is unknown, so we investigated the correlation with the dependent variable as a proxy. Our findings are quite robust to the use of different instruments and exclusion of any one of these three instruments.

[Insert Table 3 About Here]

Table 4 presents regressions for the determinants of natural log of the number of weeks of due diligence (in this Table we report first stage OLS estimates). We present two models: Model 1 includes fund dummy variables, year dummy variables, and double-clusters standard errors by fund and year, while Model 2 excludes these dummy variables and does not cluster standard

errors.<sup>7</sup> These alternative models are presented merely for a robustness check in our subsequent analyses in Tables 5 and 6.

[Insert Table 4 About Here]

The regressions in Table 4 indicate two robust determinants of due diligence. First, buyouts require less due diligence and this effect is significant in both Models 1 and 2 at the 5% and 10% levels, respectively, which is expected since buyout transactions focus more on established target companies with more readily available information and a longer track record.

Second, investors that run more funds spend more time on due diligence. This result may be attributed to the value of experience that motivates PE investors to implement a more thorough due diligence of new deals (in line with Nahata, 2008 and Yung, 2009), or to the constrained attention due to a higher number of funds managed (in line with Jääskeläinen *et al.*, 2006). We note that this latter variable is an important one, and given that it is not correlated with investee performance as discussed above it may represent a useful candidate instrumental variable. Another useful candidate as an instrument is the location of the target firm (e.g., we considered whether or not the target is located in the same region of the PE funds) or, alternatively, the geographic proximity, measured in terms of kilometric distance, of the target to its investor (in line with Tian, 2011). As robustness check purposes, we also considered other instruments (see Section 6.4. for more details) and the results are not materially different from those reported in this Section.

---

<sup>7</sup> We also considered different specifications of Models 1-2, available upon request, and the results did not materially change. For example, in Model 1, we excluded Dark and Hope variables and left the year dummies. Moreover, in Models 1-2, we controlled for other fund characteristics (e.g., number of partners, number of syndicated investors, international affiliation, lead investor status) and the results are in line with our expectations and quite robust with the models reported in this paper.

Also, there is some evidence of less due diligence in the Dark period (Model 2) and this effect is significant at the 5 % level, but this effect is not significant in Model 1 due to the inclusion of the year dummy variables. Similarly there is evidence, significant at the 10% level, of more due diligence in the Hope period, but this effect is not significant in Model 2. Preplanned IPOs have more due diligence in Model 2, but this effect is not significant in Model 1 due to the inclusion of the fund and year dummies. Model 1 highlights that older funds carry out more due diligence, arguably due to more experience, and funds with larger portfolios per manager carry out less due diligence due to a dilution in the allocation of their time and attention (in line with the results highlighted by Hamdouni, 2011 and Jääskeläinen *et al.*, 2006). However, these effects are not significant in Model 2.

## *6.2. Relationship between Due Diligence and Investment Performance*

Table 5 presents second stage estimates and includes three panels examining the impact of due diligence on the subsequent 3-year ROA (Panel A), subsequent 3-year EBITDA/Sales (Panel B), and subsequent 1- and 2-year ROA and EBITDA/Sales (Panel C). Panels A and B each present 5 different regression models to check for robustness. We include three regressions with the use of the due diligence fitted values from Model 1 in Table 4 (Models 3-5 in Panel A and Models 8-10 in Panel B), one regression with the use of the fitted values from Model 2 in Table 4 (Model 6 in Panel A and Model 11 in Panel B), as well as one regression without fitted values (i.e., no control for possible endogeneity), in Model 7 (Panel A) and Model 12 (Panel B). The Panel C regressions for 1- and 2-year ROA and EBITDA/Sales use the Table 4 Model 1 fitted values; for conciseness we do not report the same sets of models as in Panels A and B for 1- and 2-year ROA and EBITDA/Sales since the results were not materially different. Alternative specifications are available on request.

[Insert Table 5 About Here]

Our data consistently indicate that the number of weeks of due diligence is consistently associated with stronger 3-year ROA and EBITDA/Sales performance, consistent with H1. We model the effect with the use of logs to account for diminishing changes in returns associated with each extra week of due diligence. The effect is statistically significant, at least at the 10% level in each of the models in Panels A and B. The most conservative economic significance is obtained from the regressions without the endogeneity controls (Models 7 and 12). In those estimates, a 1-standard deviation increase in the weeks of due diligence from the average due diligence level of 8 weeks gives rise to a 197.44% increase in three-year ROA relative to the average three-year ROA in the sample (and this effect is smaller at 113.51% if one starts from the maximum level of weeks of due diligence of 15 weeks, and larger at 533.95% if one starts from the minimum level of due diligence of 2 weeks). Put differently, an extra four weeks of due diligence is on average associated with a doubling of three-year ROA performance.

The effect of due diligence on EBITDA/Sales is similarly consistent in all of the regression models, and the economic significance is most conservative in the models that do not correct for endogeneity. In those estimates, a 1-standard deviation increase in the weeks of due diligence from the average level of due diligence of 8 weeks gives rise to a 52.07% increase in three-year EBITDA/Sales relative to the average three-year EBITDA/Sales in the sample (and this effect is smaller at 29.94% if one starts from the maximum level of weeks of due diligence of 15 weeks, and larger at 140.82% if one starts from the minimum level of due diligence of 2 weeks).

Panel C of Table 5 shows that the impact of due diligence on EBITDA/Sales ratio is significant for the one- and two-years after investment, but the economic significance is higher

with each year up to the three-year period after investment for the comparable model (Model 8) in Panel B. Due diligence, by contrast, is statistically unrelated to ROA in the one- and two-year period after investment.

The large economic significance and consistent statistical significance of the impact of due diligence in Panels A and B is contrasted by the weak economic significance and inconsistent statistical significance of all of the control variables.

Additionally, for robustness purposes, we have considered a number of different specifications by including, in the second stage, variables that may be related to the value of experience of PE investors and, as such, may have an impact on performance, e.g.: number of funds managed, or capital under managed, or portfolio size. We have also considered specifications controlling for the value added capacity of PE investors. Additionally, we have considered new instruments, e.g., the kilometeric distance between the target and the PE investor (in line with Tian, 2011) or the time spent in performing the DD in other target firms belonging to the same industry and acquired in the same year. Results remain robust to the inclusion or exclusions of the above variables and do not materially change the main findings discussed in this Section (the robustness checks that we have performed are explained in greater detail in the Section 6.4.).

### *6.3. The Role of Different Agents Carrying Out Due Diligence*

In Table 6 we present second stage regressions for various sample-subsets according to the specific agent performing the majority of due diligence (e.g., the fund managers or external firms). The Models in Table 6 are comparable to the Models 5 and 10 in Table 5. The regressions highlight a more pronounced impact on performance associated with the due diligence carried out internally by the PE investment managers themselves, consistent with H2. When the majority of

due diligence is performed externally by law firms, accounting firms and/or consulting firms there is an insignificant relation between weeks of due diligence and performance. These findings are consistent with Table 2 (Panel A). For example, when due diligence is primarily performed by accountants, on average the performances of investee companies are worse compared to the performance of the other transactions for which no accounting firm was hired to perform the due diligence, consistent with Models 31 and 32 in Table 6.

The evidence provided in Table 6 highlights the importance for PE firms to undertake an internal due diligence. Our results highlight the existence of apparent agency costs associated with the due diligence performed externally by law firms, accounting firms, and consultancy firms, and call for future theoretical and empirical research to investigate the mechanisms to mitigate agency costs incurred in the delegation of due diligence.

[Insert Table 6 About Here]

#### *6.4. Additional Robustness Checks*

In the course of our analyses we carried out a number of preliminary robustness checks. First, we considered longer performance horizons, including four and five years. The findings were generally consistent, but to a much greater degree influenced by outliers that are more than likely unanticipated and unrelated to due diligence. Hence, we focus on 3-year performance. Second, we considered performance measures provided by the fund managers themselves versus financial statement information obtained from official sources filed in accordance with the Italian accounting rules. Our performance measures reported herein are those based on the AIDA database by Bureau Van Dijk, and we did not find major discrepancies with self-reporting in our surveys. Third, we considered other explanatory variables including but not limited to specific contractual terms described in Cumming and Zambelli (2013). The findings are robust (explicitly

shown in the Online Appendices 1 and 2 shown at the back of this paper). We note due diligence is weakly positively correlated to more detailed contracts in our data, which in part is consistent with the findings herein. We do not include these contractual analyses in the results reported herein since the causal link between contracts and due diligence is in need of further empirical testing with other datasets. Fourth, in order to evaluate whether the length of DD is affected by the involvement of external actors, we have run a number of specifications on the determinant of DD, similar to those reported in Models 1 and 2 (Table 4), by including an additional variable to control for the impact of external agents performing the due diligence. Also, we have considered other control variables, such as the size of the investee firm and the control power of the PE investor (see Section 6.4.1. for details). We found no significant correlation between the time spent on DD and the involvement of external agents performing the due diligence process. For brevity reasons we did not report these results because they do not materially change the main findings discussed in the previous sections and presented in Table 4 (they are available upon request). Fifth, we controlled for buyouts versus expansion deals in all of our analyses. The PE funds in the sample do both types of deals, and hence we include them all in the sample. The results are robust to excluding the expansion deals, although not robust to excluding the buyout deals as most of the deals are buyout deals. Furthermore, we run a number of different second-stage regression specifications in order to control for the cost of debt and the debt-to-equity ratio and results are in line with the main findings of Tables 5-6 discussed in the paper with reference to the impact on performance of DD duration and internal DD.

To further reinforce the robustness of our main results, we carried out a number of additional analyses and tests, as summarized below:

1. Isolating the effect of due diligence on performance:

- a. Control for the value added capacity of PE investors;
  - b. Control for both the value added capacity of PE investors and size of Investee Firms;
2. Treatment Effect Model (similar to Heckman selection model);
  3. Two-stage IV regression for the determinants of internal versus external due diligence;
  4. Propensity Score Matching models, comparing the impact on performance of longer and shorter DD, as well as the impact on performance of internal and external DD;
  5. Inclusion or exclusion of different instruments; adoption of a new instrument measuring the geographic distance between PE funds and their target companies (“distance km”); adoption of a new instrument created by considering the average time spent on implementing the due diligence in other target firms active in the same industry and acquired in the same year (“dd\_weeks\_OTHER”; and “ln\_dd\_weeks\_OTHER”);
  6. Inclusion of other performance measures: Return on Equity investment (ROE) and IPO exit outcomes.
  7. Inclusion of performance measures (ROA, ROE, and EBITDA/Sales) recorded at the time of exit, and the time of investment.

In the following sub-sections we report the details of the robustness checks mentioned above.

#### *6.4.1. Isolating the Effect of Due Diligence and Controlling for the Size of Target Firms*

As highlighted in the literature, private equity fund managers are actively involved in the governance and management of their portfolio companies (see, e.g., Sorensen, 2007) and the screening process may depend on the size of the company (Yung, 2009). In order to isolate the impact of DD on investees performance, we performed a number of robustness tests aimed at considering the value added capacity of the PE investors, as well as the size of their target firms

(see Tables 7-8). Our results remain robust to the inclusion of these additional control variables. In particular, consistent with the models reported in Tables 4-5, in Table 7 we show first-stage estimates related to the determinants of due diligence and in Table 8 (Panels A, B and C) we report second-stage estimates on the impact of the due diligence on investee performance. In all Models shown in Tables 7 and 8, we included a variable that is aimed at capturing the level of involvement and control power played by the PE fund manager. In line with Cumming and Johan (2013), as a proxy for the PE involvement, we have considered an index given by the sum of veto and control rights held by the PE investors (see Table 1 for more details on the specific control and veto rights included). Among the control rights, we have considered the right to choose and substitute the CEO, the right to add board members, the right to retain board control, as well as other exit rights, such as the first refusal in sale, and IPO registration rights. Among the veto rights, we have considered the veto power of the PE investor over various decisions, such as the issuance of equity, control changes, asset purchase or asset sale.<sup>8</sup> We have included the veto rights because they allow the PE fund manager to influence the outcome of a number of important business decisions. In Table 7 we show the first stage estimates, while in Table 8 we report the second stage estimates of the impact of due diligence on investee performance, after controlling for the PE involvement and the size of the target firms (in terms of log of the number of employees).<sup>9</sup> The results reported in Tables 7-8 are consistent with our main findings discussed in the previous sections and further reinforce the results reported in Tables 4-5.<sup>10</sup>

[Insert Tables 7-8 here]

---

<sup>8</sup> For a recent review of the control and veto rights held by PE investors, see Zambelli (2014).

<sup>9</sup> The number of employees was not available for all companies.

<sup>10</sup> In Table 8 we show the impact of due diligence effort on investee performance, after controlling for the PE involvement and value added capacity. We also controlled for the size of the target firms (in terms of number of employees). The number of employees was not available for all companies. For space reasons, we decided to not include the additional robustness checks that control for the different size of target firms given the fact that the results from these additional robustness tests do not materially change the main findings discussed in the paper. Results are available upon request.

#### 6.4.2. *Considering Treatment Effect Models for potential sample selection biases*

The decision of performing the majority of DD internally (rather than externally) is a choice variable and this may raise sample selection biases.

In order to address the above issues, we have employed a treatment effect method (similar to a Heckman selection model)<sup>11</sup> by estimating, in the first step, the probability of having an internal due diligence (as a function of investee location and fund characteristics, such as portfolio size and legal structure) and, in the second step, the related outcomes in terms of impact on firm performance, given the results in the first step. In particular, in Table 9 we report the second stage estimates of the treatment effect model for the decision of implementing an internal DD (for space reasons, the first stage estimates for the selection equation are not included). In Models 1, 2 and 3 we show the impact of DD on ROA 3Y, 2Y, and 1Y differences; in Models 4, 5 and 6 we show the impact of DD on EBTDA/sales 3Y, 2Y, and 1Y differences, respectively. It is worth noting that in the first-step we have considered specifications with only one variable (e.g., the geographic distance between the PE fund and target) to keep the model parsimonious, as well as specifications with additional variables related to fund characteristics (e.g., lead investor, capital under management, fund legal structure, and number of portfolio firms). Given the recent evidence on the impact of spatial proximity on VC behavior (see, e.g., Tian, 2011) and contract design (e.g., Hirsch and Sharifzadeh, 2009; Cumming and Johan, 2013), it is reasonable to expect that the geographic distance between the fund and the target may affect the type of due diligence (internal versus external).<sup>12</sup> We have also considered specifications with additional selection

---

<sup>11</sup> The model is a treatment model (similar to a Heckman model) with the “treatreg” function in Stata. A nice feature of the treatreg function is that it does not have the same restriction as the Heckman regression to have all of the same variables in the first step regression, plus extra variables.

<sup>12</sup> In order to consider the recent evidence (see, e.g., Tian, 2011) on the positive impact of geographic proximity on the monitoring of target firms and their performance, in our treatment effect model the variable related to spatial proximity has been included both in the selection equation and in the outcome equation. In our data, the geographic

criteria related to fund characteristics (e.g., capital under management) to take into account the evidence shown in Brown *et al.* (2008). The second-step results are extremely similar to what is reported in the paper without the selection equation. Likewise, the findings remain robust to the inclusion of one or more selection criteria to the first-step regression equation (for details, see Table 9).

[Insert Table 9 here]

In order to take into account potential selection biases regarding the internal versus external due diligence, we ran additional robustness tests (not reported in the paper for space reasons, but available upon request). For example, we have considered two-step IV methods for the determinants of internal versus external due diligence, with the use of instruments (instead of a treatment specification) as in the case discussed for the number of weeks of due diligence. The results do not materially change. In particular, we considered two-stage IV regressions by estimating, in the first step, the determinants of the internal versus external due diligence and, in the second stage, the impact on performance of the internal DD predicted in the first step. In the second stage, we have also considered the predicted value of the due diligence time, driven from Models 1 and 2 reported in Table 4 of the paper. The first step regression on the determinants of internal due diligence shows (as the most robust finding) that bigger funds (e.g., funds with larger portfolio sizes per manager) are more likely to delegate the majority of the due diligence to external agents, and this is in line with the evidence shown by Brown *et al.* (2008). The results of the first-step estimates do not materially change the main findings of our study. Likewise, the second-step estimates always highlight a positive and significant relationship between due diligence time and firm performance. The fitted values for the internal due diligence included in

---

proximity is significant only in the first step-regression (as a determinant of internal due diligence) but not in the second step.

the second step are statistically insignificant in all the specifications included in Table 5 Panels A, B and C, regardless of the specification adopted in the first step. Similarly, the simple variable for internal versus external due diligence (without fitted values) is statistically insignificant in Table 5, and does not change the inferences drawn regarding the weeks of due diligence. Hence, we do not include such a variable in the reported results to keep the models as parsimonious as possible (the results are available upon request).

Ultimately, as an additional robustness check, we considered Propensity Score Matching Models related to the impact of long due diligence (i.e., longer than 10 weeks) versus short due diligence. As shown in Table 10, the Average Treatment Effect (ATE) of longer due diligence is positive and significant, in line with the main findings discussed in the paper.<sup>13</sup>

[Insert Table 10 here]

#### 6.4.3. *Considering other Performance Measures*

For robustness check purposes, we have considered other performance measures, such as IRR, Return on Equity (ROE), and IPO exit outcomes.

Regarding IRRs, however, we have information only for a subsample in our data, as many of the deals were not exited at the time of data collection and, at the time of our survey on investee performance, the IRR was not provided (or not publicly available) for a number of exited investments. Therefore, we are effectively restricted to using ROA and EBITDA/Sales which were confirmed by AIDA database and auditor reports in order to use the full sample (and our choice is in line with Cao, 2013 and Richard *et al.*, 2009). It is worth noting that different measures of operating profitability can be adopted. For example, Florin (2005) employs the EBIT

---

<sup>13</sup> We have also considered Propensity Matching Models with reference to the internal versus external due diligence and we obtained results in line with the main findings discussed in the paper.

to Sales ratio; Kabir and Roosenboom (2003) employ both the EBIT to Sales ratio and the EBITDA to Sales ratio. However, the latter ratio is more appropriate to assess the operating profit margin from a strategic and managerial point of view, as the EBITDA represents the portion of firm's operating profit that is not affected by depreciation, amortization, interest and taxes. Moreover, since the EBITDA is adjusted to remove the impact of noncash expenses (e.g., depreciation and amortization), the profit margin expressed in terms of EBITDA/Sales is also more appropriate to better evaluate the firm efficiency (see, e.g., Richard *et al.*, 2009).

Given the relevant number of missing values related to IRRs, as an approximation, for robustness check purposes we have collected additional information from AIDA database on the Return on Equity (ROE) of all target firms included in our dataset and estimated the impact of DD duration on ROE. Additionally, we have considered other performance measures represented by the IPO exit outcomes (collected from our third survey and confirmed by the information publicly available in "Borsa Italiana"). Results are shown in Table 11 (Panel A). Ultimately, in Panel B of Table 11, we have considered the investee performance at the time of exit (instead of a three-year period). Since the decision to exit is a non-random event, we also included specifications with a treatment of potential sample selection for the exit decision by predicting, in the first step, the probability of an exit (as a function of the investment year) and estimating, in the second step, the outcome from that exit (in terms of investee performance).<sup>14</sup> The results reported in Table 11 are in line with the main findings provided in the paper. A thorough DD is

---

<sup>14</sup> In the second stage, we have considered the predicted value of the due diligence time, driven from Models 1 and 2 reported in Table 4 of the paper.

associated with higher IPO exit outcomes, higher ROE, as well as higher firm performance at the time of exit.<sup>15</sup>

[Insert Table 11, Panels A, B]

#### 6.4.4. *Different Instruments*

For robustness check purposes, we have considered other specifications such as excluding year dummy variables in Models 3 and 4 while leaving the dark and hope dummies, and the effect of due diligence remains highly significant. Additionally, we considered different second-stage regression specifications, by including in the second stage variables related to investor characteristics (e.g., fund age, capital under management and number of funds managed by the PE organization at the time of the first investment in the target firm). We ran a number of different specifications and overall the impact of due diligence effort on firm performance remains highly significant. The second stage estimates reported in Panel A of Table 12 are in line with the findings discussed in the paper and presented in Table 5. Overall, our main findings are robust to the inclusion or exclusion of the above control variables (see Table 12 Panel A).

We further included other possible instruments to control for endogeneity and our findings are quite robust to the inclusion and exclusion of different instruments. For example, we ran the regression specifications shown in Tables 4-5 by including a new instrument based on the kilometric distance between the fund and the target company, in line with Tian (2011). The results from the first and second stage regressions are consistent with the main findings discussed

---

<sup>15</sup> It is worth noting that, for robustness check purposes, we also considered the impact of DD on performance at the time of first investment. The findings do not show significantly different results and the external DD is associated with worse firm performance. Ultimately, with reference to the internal versus external DD, we have also considered the role of PE size in terms of capital under management, number of firms included in the portfolio and number of funds managed by PE investors. The results are consistent with our main findings discussed in the paper and internal DD remains associated with better firm performance (both in terms of ROA three-year difference and EBITDA/Sales three-year difference).

in the paper (see Table 12, Panel B). Ultimately, we considered the adoption of an alternative new instrument given by the time spent on performing the due diligence in other target firms belonging to the same industry and acquired in the same year (see Table 12, Panel C). The impact of due diligence effort on firm performance remains relevant and significant and the main finding discussed in the paper are confirmed.

[Insert Table 12, Panels A – B - C]

## 7. Conclusions

In this paper we have investigated the efficacy of due diligence and quantified the time-value of due diligence in the context of private equity (PE) investments. We have shown a link between the time spent on due diligence and the future performance of investee firms, measured in terms of changes in the return on assets (ROA) and EBITDA/sales ratios over the first three years of the investment.

Very few academic studies, if any, have analyzed the economic value of due diligence and its crucial role in predicting better future performance of the investee firms. Based on a novel and unique hand-collected dataset comprising the majority of PE investors in Italy, our results show that due diligence enables selection of better investees in the portfolio and strongly support the view that a diligent due diligence is associated with improved firm performance. Moreover, our data show that the due diligence carried out internally by fund managers has a more pronounced impact on performance. No significant impact emerges with reference to the due diligence performed by external agents, i.e., accounting firms, law firms or consultants.

Our study reinforces the evidence highlighted by Brown *et al.* (2008) who argue that due diligence is a source of alpha for hedge funds. Likewise, the due diligence has a crucial role and a high economic value in the context of PE.

Overall, our findings contribute to advance the knowledge on the role of the selection and evaluation process underlying the acquisition of a target firm. One important implication for PE investors and advisors derived from our study is that, in a PE setting, the time spent on due diligence is a source of value in terms of observed better future performance of investee firms. A second important implication for PE fund managers is that the time spent on due diligence is especially worth it when the majority of that time is spent in implementing a DD internally. Ultimately, our findings suggest the existence of apparent agency costs underlying the due diligence delegated to external agents. More theoretical and empirical research is needed in order to enrich the knowledge on agency costs associated with the delegation of due diligence, especially in the context of PE where the opportunity cost of time is enormous and investors may be tempted to rush the evaluation process underlying the due diligence or to delegate it outside in order to allocate more attention to managing and adding value to their existing portfolio firms. Further research could likewise examine bargaining over contractual terms during the due diligence process to better understand how contracts are negotiated in practice and their impact on performance.

**Table 1. Definitions of Variables and Summary Statistics**

This table defines the variables and provides summary statistics. The full sample comprises of 178 observations, of which 116 are leveraged buyouts and 63 expansion financing deals. Summary statistics are provided for the entire sample. The data derive from the survey and interviews with the PE investors carried out in 2005, as described in the body of the paper.

Variable	Definition	Number of Observations	Mean	Median	Standard Deviation	Min	Max
<i>Dependent Variables</i>							
<b>Firm Performance Indicators</b>							
Return on Asset (RoA) Three-Year Difference	Difference (in %) between RoA at the third year after the investment and RoA at Investment Date. Source: AIDA database by Bureau Van Dijk	178	0.77	0.86	13.27	-71.16	55.80
Ebitda/Sales Three-Year Difference	Difference between Ebitda/Sales at the third year after the investment and Ebitda/Sales at Investment Date. Source: AIDA database by Bureau Van Dijk	178	2.65	1.87	12.12	-31.02	73.39
Return on Asset Two-Year Difference	Difference (in %) between the ROA at the second year after the investment and the RoA at the investment date. Source: AIDA database by Bureau Van Dijk	178	-0.27	0.10	9.90	-71	34.9
Ebitda/Sales Two-Year Difference	Difference between Ebitda/Sales at the second year after the investment and Ebitda/Sales at the investment date. Source: AIDA database by Bureau Van Dijk	178	1.58	1.38	8.62	-31.02	65.08
Return on Asset One-Year Difference	Difference (in %) between the ROA at the first year after the investment and the ROA at the investment date. Source: AIDA database by Bureau Van Dijk	178	0.73	0.21	7.59	-38.31	38.52
Ebitda/Sales One-Year Difference	Difference between Ebitda/Sales at the first year after the investment and Ebitda/Sales at the investment date. Source: AIDA database by Bureau Van Dijk	178	1.15	0.82	5.98	-18.87	53.65
<i>Key-Explanatory Variables</i>							
<b>Due Diligence Length and Types</b>							
Ln (Number of Weeks of Due Diligence)	Natural Log. of number of weeks actively spent on due diligence. Source: Author's surveys	178	1.93	1.95	0.54	0.69	2.71
Prevalent Internal Fund Due Diligence	A dummy variable equal to 1 if the PE investor spent more than half of the time doing due diligence checks themselves as opposed to using consultants, lawyers, and/or accountants. Source: Author's surveys	178	0.47	0	0.50	0	1
Consultants' Due Diligence	A dummy variable equal to 1 if the PE delegated the majority of due diligence to a consultancy firm specialized in audit, tax, and advisory services (e.g., KPMG). Source: Author's surveys	178	0.66	1	0.48	0	1
Legal Due Diligence	A dummy variable equal to 1 if a legal due diligence was performed by a professional lawyer. Source: Author's surveys	178	0.68	1	0.47	0	1
Accountants' Due Diligence	A dummy variable equal to 1 if the PE investor delegated the majority of due diligence to a professional chartered accountant. Source: Author's surveys	178	0.11	0	0.31	0	1
<i>Other Control Variables</i>							
<b>Market Conditions</b>							
12-Month Stock Market Return	The return on the stock market for the 3–12 month horizon preceding the investment date. Source: MSCI	178	0.08	0.14	0.17	-0.32	0.41
MSCI Annual Return over Investment Horizon	The annualized public equities return for Italy over the contemporaneous investment horizon. Source: MSCI	178	-0.05	-0.15	0.33	-0.57	0.72
<b>Legal Settings</b> (Source: Cumming and Zambelli, 2010, 2013)							
Dark Period	A dummy variable equal to 1 for the "Dark" period during which leveraged buyouts are illegal (January 1999– September 2001 for the transactions in the data set).	178	0.21	0.00	0.41	0.00	1.00

Hope Period	A dummy variable equal to 1 for the “Hope” period during which it is announced by the Italian Parliament that buyouts will soon be legal (October 2001 – December 2003).	178	0.31	0.00	0.47	0.00	1.00
Sun Period	A dummy variable equal to 1 for the “Sun” period during which buyouts are legal (January 2004, and ending at July 2006 in the data set).	178	0.48	0.00	0.50	0.00	1.00
<b>Investee Characteristics</b>							
Industry Market / Book	The industry market-to- book value for publicly traded firms at the time of investment.	178	2.42	1.88	1.66	0.38	11.58
Geographic proximity (Same Region)	Dummy variable equal to 1 if the investee firm is located in the same region of the PE investor.	178	0.31	0.00	0.46	0.00	1.00
<b>Deal Structure Characteristics &amp; Value Added Capacity of PE investors</b>							
Level of PE control and involvement (Sum of Control and Veto Rights)	The sum of control and veto rights contractually held by the PE investor (i.e., right to choose board members, right to retain board control, right to add board members, right to choose the CEO and other key managers, right to substitute the CEO and key managers, right to add coinvestors, drag along, redemption, right of first refusal, cosale, liquidation rights, ipo rights, veto on issuance of equity, veto on asset purchase, veto on asset sale, and veto on ownership changes).	178	10	12	3.7	1	16
<b>Investor Characteristics</b> (Source: Cumming and Zambelli, 2010, 2013)							
Age of PE investor	The age of the fund in years from date of formation to date of first investment in the investee firm.	178	5.68	4.00	8.51	0.00	74.00
No. of Funds Under Management	Number of funds managed by the same PE firm.	178	1.88	1.00	1.44	1.00	7.00
Limited Partnership	A dummy variable equal to 1 for a limited partnership fund.	178	0.545	1.000	0.499	0	1
Portfolio Size per Manager	The portfolio size (number of investees) per manager at the time of first investment	178	2.47	1.40	5.40	0.50	37.50
<b>Investment Characteristics</b> (Source: Cumming and Zambelli, 2010, 2013)							
Buyout	Dummy variable equal to 1 if the transaction is a leveraged buyout (LBO).	178	0.65	1.00	0.48	0.00	1.00
Investment Value	The total amount invested by the PE investor as at July 2006.	178	9685	4450	21254	90	183400
Preplanned IPO	A dummy variable equal to 1 if the PE investor preplanned the IPO.	178	0.31	0.00	0.46	0.00	1.00
Preplanned Trade Sale	A dummy variable equal to 1 if the PE investor preplanned a trade sale.	178	0.38	0.00	0.49	0.00	1.00
Ebitda/Sales at the Investment Year	Ebitda/Investment Ratio at the Investment Year.	178	10.33	10.00	8.61	-52.19	41.41
Syndication	The number of syndicated PE investors.	178	1.067	1.000	1.201	0	6

**Table 2. Comparison of Means and Median Tests**

This table compares the mean and median statistics for the differences on Return on Asset after 1, 2, or 3 years from the investment date. Variables are defined in Table 1. Panel A focuses on the length of due diligence; Panels B-E focus on the types of due diligence employed. Panels F-G focus on the due diligence time spent over the different legal setting characterizing the Italian market. For medians we use a Wilcoxon test; for means we adopt a standard t-test. The superscripts \*, \*\*, and \*\*\* indicate statistical significance at the 10%, 5% and 1% levels, respectively.

**Table 3. Correlation Matrix**

This table presents correlations across select dependent variables, potentially endogenous due diligence variables, potential instruments and other explanatory variables. Correlations greater than 0.13, 0.15 and 0.20 in absolute value are statistically significant at the 10%, 5% and 1% levels, respectively. Correlations greater than 0.15 in absolute value are highlighted with an underline. Correlations among potential instruments that are significant at the 5% level with the number of weeks of due diligence but not the two main dependent variables (EBIT/Sales Difference and ROA Difference) are highlighted in bold.

**Table 6. Regression Analyses for Different Agents Carrying Out Due Diligence**

This table presents OLS estimates of the impact of due diligence on Three-Year ROA in Panel A and EBITDA / Sales in Panel B. Regressions are based on the different subsamples for different agents carrying out due diligence: primarily the fund, whether or not consultants are used, whether or not external law firms are used, and whether or not external accounting firms are used. Estimates are for the difference between the year 3 performance values versus the year of investment values. Variables are as defined in Table 1. Where variables are excluded in the regressions it was due to necessity in the subsamples (e.g., in the case of consultants in the Dark period, for example). \*, \*\*, \*\*\* Significant at the 10%, 5% and 1% levels, respectively.

**Table 7. First Stage Regressions on the determinants of Due Diligence duration, controlling for the value added capacity of PE investors**

This Table presents First-stage OLS estimates of the log of the number of weeks considering the impact of the controlling power of the PE investor and the size of target firms. Variables are as defined in Table 1. \*, \*\*, \*\*\* Significant at the 10%, 5%, and 1% levels, respectively.

**Table 9. Treatment Effect Models for the decision of implementing an Internal DD (second-stage estimates)**

This Table shows the estimates from a treatment model, with the first stage (not reported) modeling the probability of having an internal DD as a function of the kilometric distance between the target and the fund, the portfolio size, and fund characteristics, and the second stage (reported) determining the factors that affect the performance of investee firms, given the results in the first stage. T-statistics in parentheses. \*, \*\*, \*\*\* Significant at the 10%, 5%, and 1% levels, respectively.

**Table 10. Propensity Score Matching for long DD versus shorter DD**

This Table shows results of Propensity Score Matching models for long DD (grater than 10 weeks) versus shorter DD. Models 1-2 and 5 consider the following observable matching information: MSCI return over horizon, Dark, Hope, buyout dummy, Market / Book, fund age, distance in km between target and fund, lead investor dummy; Models 3-4 and 6 consider the following observable information: MSCI return over horizon, Dark, Hope, buyout dummy, Market / Book. Model 6 considers the following observable information: MSCI return over horizon, and Market / Book.

Long vs. short DD Average Treatment Effect (ATE)	Impact on Firm Performance using Propensity Score Matching Model

**Table 11. Impact of DD Duration on Other Performance Measures and Other Performance Timing**

This Table presents second-stage estimates of the impact of DD duration on other performance measures. Panel A shows the impact on IPO exit outcomes (Models 1-3), as well as the impact on three-year ROE differences (Model 4 is similar to the specification presented in Model 5 of Table 5; Models 5-6 are similar to the specification presented in Model 6, Table 5). Panel B shows the impact on ROA, ROE and EBITDA/SALES recorded at the time of exit. Variables are defined in Table 1. T-statistics in parentheses. \*, \*\*, \*\*\* Significant at the 10%, 5%, and 1% levels, respectively.

**Table 12. Robustness checks considering different type of instruments**

This Table reports second-stage estimates showing the impact of DD duration on firm performance by considering different instruments. Panel A considers the inclusion in the second stage of different types of fund characteristics (e.g., number of funds managed, number of portfolio firms). Panel B considers the impact on firm performance derived by the adoption of a new instrument (i.e., the kilometeric distance between the fund and the target company). Panel C considers the adoption of another alternative new instrument given by the time spent on performing the due diligence in other target firms belonging to the same industry and acquired in the same year. T-statistics in parentheses. \*, \*\*, \*\*\* Significant at the 10%, 5%, and 1% levels, respectively.

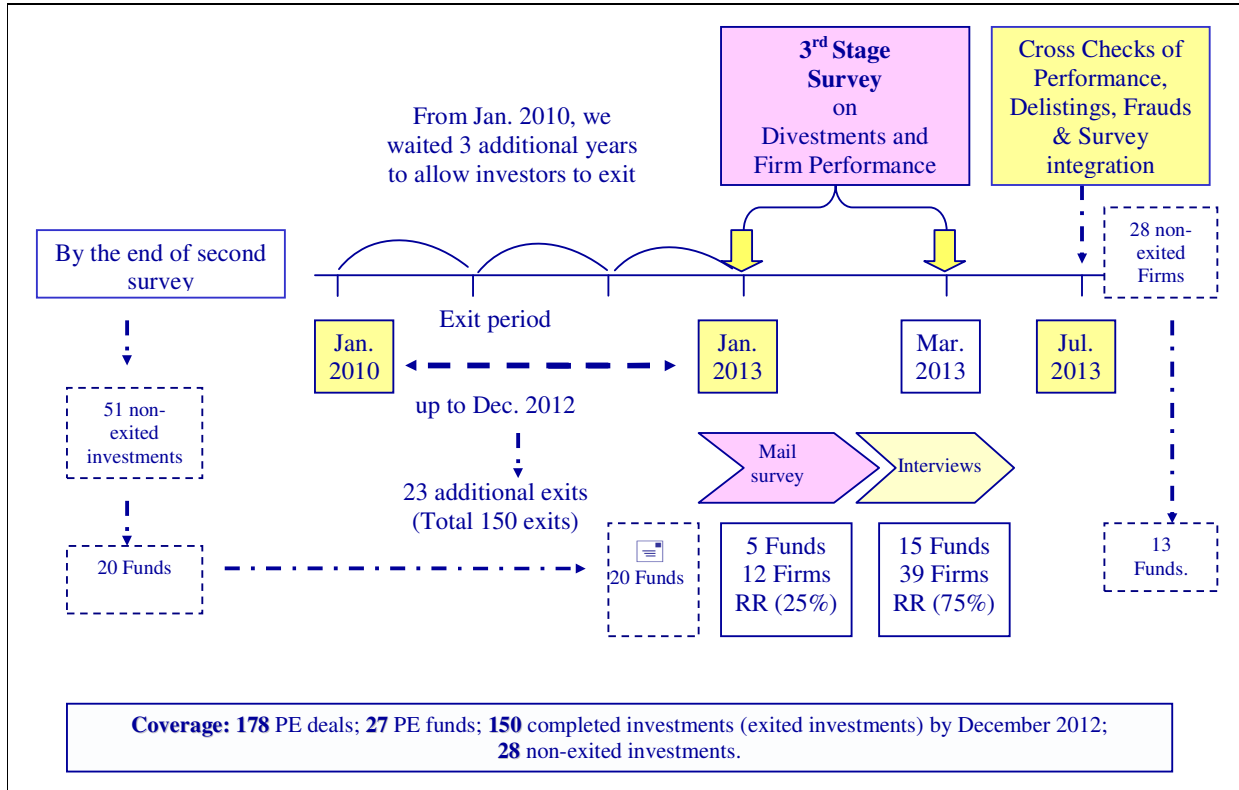

**Figure 1. Survey Procedure and Timing**

This Figure summarizes the three-stage survey employed to collect the data underlying this paper.

Part A

Part B

## **APPENDIX: Data Collection, Response Rate and Representativeness of our Database**

In this section we describe the methodology employed to collect our data, as well as present summary statistics of the PE investments carried out in Italy over the 1999-2006 period, and the associated divestments occurred over the 2000-2012 period. Part A of this Appendix describes the methodology underlying our dataset. It describes in greater detail the survey procedure, the response rate we obtained and the survey-integrations we carried out to maximize the representativeness of our ultimate sample. Part B discusses sample representativeness by describing a number of representativeness tests and potential sample selection bias.

### **Part A. Data Collection Methods**

The primary source of information underlying our database is represented by a three-stage survey of PE deals carried out from 1999 to 2006 (investment period), and PE divestments realized from 2000 to 2012 (divestment period).

#### *(a) Survey Procedure*

We collected the data by undertaking a three-stage survey of international and local venture capitalists actively involved in Italy over the 1999-2006 period. For each survey we employed a sequential mixed mode (SMM) survey approach (see De Leeuw 2005 and Dillman *et al.* 2009 for details), in combination with the “Total Design Method” (TDM), developed by Dillman (1978) specifically for mail and telephone surveys. The sequential mixed mode survey (SMM) is a particular survey procedure that recommends the adoption of a different survey mode in sequential phases.<sup>16</sup> To better highlight the research framework and time frame underlying our study, in the following sub-section we summarize the entire survey procedure employed to collect our database.

---

<sup>16</sup> With the sequential mixed mode approach, the non respondents to a mail survey (phase 1) are contacted and requested to answer the questionnaire through a different survey mode, e.g., web survey (phase 2). Thereafter, the non respondents of phase 2 are contacted and requested to answer the questionnaire through a different mode (e.g., a telephone or a face-to-face interview). Recent studies show that this survey methodology significantly improves the response rate (see, e.g., De Leeuw, 2005; Dillman *et al.*, 2009).

**1<sup>st</sup> Survey** - In October 2005 we prepared a first survey on PE investment cycle (characterized by a four-page questionnaire) and conducted a pilot study in order to test its efficacy and clearness. The feedbacks on our pilot study helped us review the questionnaire. The ultimate version of the questionnaire was sent in December 2005. In order to minimize potential sample biases, we sent the questionnaire to all members of the Italian Venture Capital Association (AIFI), which at that time recorded 88 full members.<sup>17</sup> In the first place, we administered our survey by post and devoted particular attention to following all the steps highlighted by Dillman (1978). The purpose of our first survey was to gather detailed and unique information on investment characteristics, screening criteria of target firms, due diligence procedure, deal structure and governance mechanisms employed by international and local PE investors active in Italy, as well as exit rights and exit expectations. After eliminating double-counted investors and various non-applicable replies that we received in the subsequently weeks (e.g., some investors were new, other investors were not active in the PE sector but only in the early stage sector), we identified 57 investors actively involved in the PE industry. This number was in line with the number of active investors published by the PEM database and PEM Statistics in 2005. After performing our mail survey, only 5 PE investors replied (response rate of 9%) and provided us with detailed information on 19 target firms. In line with the suggestions of Dillman *et al.* (2009), a few months later we contacted the non respondents to the mail survey and asked them to answer the questionnaire via fax (or e-mail). Thereafter, 8 PE investors replied (response rate of 14%) providing us with

---

<sup>17</sup> According to AIFI statistics published in October 2005, the total number of AIFI members was 88. According to the PEM database, the total number of investors actively involved in the PE sector was lower (57). However, the information about the specific identity of the investors active in the PE sector was not publicly available. Therefore, we decided to send the questionnaire to all 88 AIFI members, being aware of the fact that this list was not entirely applicable to our survey (some investors were new, others were not actively involved in the PE industry because they were specialized in start-up financing only). For our mail survey, we followed all the steps and suggestions recommended by Dillman (1978), devoting particular attention on the content of the package that was sent to each investor along with the questionnaire. Each investor received a package containing: a four-page questionnaire, a cover letter containing the motivation underlying the research project and a presentation of the authors' main research; a signed confidential agreement; a glossary of the PE terminology included in the questionnaire, and a reward promise made by the authors in terms of follow-up reports summarizing the results of the survey.

complete information on additional 49 PE investee firms. In June 2006, we contacted the non-respondents once again in order to ask their permission to perform a face-to-face interview in their office. Additional 14 investors (response rate 24%) agreed to partake in our survey and provided full information about 110 target firms. By the end of August 2006, we completed the interview process related to our first survey and collected detailed data on PE investments in 178 target firms acquired in Italy over the period from January 1999 to 2006 (second quarter). For each investee firm, we gathered information on target companies, screening procedure, investor rights and governance mechanisms employed by PE investors.

**2<sup>nd</sup> Survey** - Normally, PE fund managers exit their investments in 3-5 years (see, e.g., Cumming and Johan 2009). In order to investigate exit outcomes, we waited for another three years and a half to allow PE funds to exit their investee firms. In January 2010, we started a second survey of the same 27 PE investors included in our sample, with the aim of collecting information on the development of the investee firms included in our sample and gather additional information on exited investments, associated investment returns (in terms of IRR), and exit expectations for the non-exited investments. Upon request, 19 PE firms replied to our second survey directly via e-mail (response rate of 70%), providing us with information on the performance of their investments in 93 target firms. The remaining 8 PE firms (30%) agreed to answer the second survey only through a face-to-face interview. By the end of July 2010, we completed the scheduled interviews and we collected information on exit outcomes of additional 85 target firms. By the end of our second survey, we collected detailed information on 127 divestments, which occurred from January 2000 to December 2009. For each divestment we recorded the following information: exit routes (i.e., IPO, trade sale, secondary sale, buyback, write-off), divestment values, exit years, and associated investor returns (in terms of IRR). For each non-exited investments, we gathered information on exit expectations of PE investors (e.g., expected year, expected divestment route and value, as well as expected IRR returns). By the end of our second survey, in December 2010, our dataset included 51 non-exited investments performed by 20 PE funds.

**3<sup>rd</sup> Survey** - In order to have a more complete picture of the exited investments, we waited for three more years to allow the remaining PE funds to exit their investee firms. In January 2013, we started our third survey by contacting the remaining 20 PE investors included in our database. Our purpose was to collect information on additional divestments, exit routes, exit outcomes, and firm performances. Upon request, 5 PE investors replied promptly to our mail survey, providing us with detailed information on their divestments in 12 target firms. The remaining 15 investors accepted to answer the questionnaire through an interview, after which we collected information on 39 target firms. By the end of our third survey (March 2013), our database included 150 divestments, occurred over the period from January 2000 to December 2012. We also monitored the performance of the venture-backed firms that went public over the same divestment year, and collected information on potential post-IPO bankruptcies, legal investigations, and the delisting occurred until December 2012.

*(b) Survey Integration and Response Rates*

In order to validate, correct and integrate the information gathered through our three-stage survey, we considered a number of secondary sources. First, we compared our data with the Statistics Report provided by the Italian Venture Capital Association (AIFI), available at the AIFI website, in combination with two additional private equity databases: a) the Private Equity Monitor (PEM<sup>®</sup>) dataset, developed by AIFI in association with Università Cattaneo – LIUC, and b) Venture Economics database. With this first comparison we cross-checked, and eventually corrected, the information we received on investment characteristics (i.e., target firm, location, investment year, industry, invested amounts and divestment values). Second, we considered the AIDA database by Bureau Van Dijk to collect information on financial performances of the target firms included in our database, e.g., Return on Assets (ROA) Ratios, and EBITDA to sales ratios, as well as the balance sheets of the target firms included in our database, their Debt to Equity ratios, and the cost of debt over the 1999-2006 period. Third, we collected further information on market conditions, by looking at Datastream by the Thomson Corporation, MSCI database, and Borsa Italiana. We

integrated our database with important control variables related to market returns, and industry market to book values. Fourth, we considered additional sources of information in order to make sure that our dataset included the majority of the investments listed in each fund website, as well as minimize potential sample biases and avoid the risk of having a sample biased toward the most successful PE deals. Among these additional sources, we checked investor websites, financial reports provided by investors, and the most relevant economic press release. In so doing, we gathered important information about fund characteristics (i.e., age, location, portfolio size, capital under management, legal structure, independency, number of partners, executives and directors).

The response rates associated with our survey are reported in Table A.1, Panel A. Despite the difficulties associated with the implementation of a three-stage survey on confidential information, we obtained a high response rate. With reference to the PE market as a whole, we obtained a total response rate of 47% (27 over 57 investors actively involved in the PE industry in 2005). Considering the buyout sub-sector, our survey covers 84% of the buyout investors active in Italy by the end of 2005 (21 over 25 PE funds). Considering the total number of buyout transactions reported in the PEM<sup>®</sup> Statistics, our dataset comprises 38% of the buyouts carried out in Italy over the 1999-2006 period (see Table A.1, Panel A). These response rates compare favorably with previous surveys in the finance field (e.g., Brau and Fawcett, 2006, who received a total response rate of 19%; Graham and Harvey, 2001, who obtained a 9% response rate).

## **Part B. Sample characteristics and Sample Representativeness**

Our ultimate dataset includes 178 target firms, acquired by 27 private equity organizations covering approximately 85% of the buyout investors operating in Italy from 1999 to 2006 investment period. The data include detailed information on 150 exits realized over the 2000-2012 divestment period. Our dataset includes both quantitative and qualitative information about: a) investment and divestment values; b) deal structure; c) valuation models employed by investors; d) returns associated with the exited investments; d) performance of the target firms (from the

investment date up to three years after the investment); e) screening criteria employed by PE investors to screen out non attractive investment opportunities; these criteria are ranked on a scale of 1–5 in order to capture the level of relevance associated with each criterion, as perceived by PE investors; f) financial forms employed by PE investors, as well as the control and cash flow rights retained by them (including exit rights and events upon which a reallocation of cash flow and control right may occur).

To evaluate the representativeness of our sample, we compared our dataset with both AIFI Statistics Reports and the Private Equity Monitor (PEM<sup>®</sup>) database, which includes generic and standard information about all PE deals realized in Italy. Table A.1 shows the various comparison tests we performed between the PEM data (or AIFI data) and our sample to ensure the representativeness of our dataset (see Table A.1 Panels B–G). In particular, Panels B–D compare our database with the PEM sample, while Panels E–G compare our data with the AIFI Statistics Reports. We performed several comparison tests with respect to various sample characteristics: target firm location (Panel B); industry distribution of PE transactions (Panel C, part 1) and buyouts (Panel C, part 2); yearly distribution of PE investments over the 1999-2006 period (Panel D); exit distribution of PE divestments over the 2000-2012 period (Panel E); IPO distribution over the 2000-2012 time horizon (Panel F); and write-off distribution (Panel G). As highlighted in Table A.1 (Panels B–G), our sample is quite similar to the datasets provided by AIFI and PEM. Apart from a few exceptions, no statistically significant differences exist between our dataset and the PEM database (Panels B–D). Similar patterns emerge when comparing our dataset with the AIFI Statistics Reports (Panels E–G): the comparison tests do not show statistically significant differences, apart from a few rare cases. For example, Panels B and C focus on the location distribution of target firms (Panel B) and industry distribution of PE investments realized in Italy (Panel C). The comparison tests show no significant differences between Private Equity Monitor

(PEM) data and our sample.<sup>18</sup> Similar trends are observed in Panel E, which focuses on distribution of divestments realized from 2000 to 2012. In terms of exit distribution, the comparison tests in Panel E do not show statistically significant differences. In terms of yearly distribution of buyout investments (Panel D), IPO distribution (Panel F) and write-off distribution (Panel G), the comparison tests indicate scant statistical significance in terms of differences between our sample and the PEM<sup>®</sup> or AIFI data. Panel D shows that the proportion of buyouts is similar in both datasets, apart from the years of 2000 and 2004, for which our sample comprises a higher proportion of buyouts. The comparison tests in Panels F do not highlight significant differences except for the years of 2003 and 2004, for which AIFI Statistics report higher proportion of IPO exits. Similar conclusions can be driven by looking at Panel G, which compares the write-off distribution related to AIFI dataset with the one related to our sample. In Panel G, no relevant differences emerge, aside from the sole exception of the year 2007, for which our database report a higher percentage of write off.

[Insert Table A.1 About Here]

---

<sup>18</sup> It is worth noting that the PEM<sup>®</sup> data highlighted in Panels B–D cover the period 1999–2003, the years for which the information is available. For Panels B–D, comparison tests in our sample are reported for the 1999–2006 period. We also performed comparison tests with reference to the shorter period (1999–2003) and did not observe materially different results.

**Table A.1. Representativeness Tests**

This Table presents comparison of proportions tests between the survey data used in this paper relative to the data reported by the PEM<sup>®</sup> database, published by the Italian Venture Capital and Private Equity Association (AIFI) in association with the “Masters in Merchant Banking” team of Università Carlo Cattaneo (LIUC). To show that the data are representative of the population, we perform various comparison tests (see Panels B-G). Panel A summarizes the response rate and coverage for our sample. Panel B compares the proportion of investments by location, Panel C compares the industry sectors for all types of PE investments and buyout transactions, Panel D compares the years of investment, Panel E compares the exit year distributions of investments, Panel F compares the IPO exit years, Panel G compares the write-off exit years. The \*, \*\*, \*\*\* indicate statistical significance at the 10%, 5% and 1% levels, respectively.
